#### Abstract

The parameters of sporadic  $D_s$  layer of electric conductivity caused by ultraenergetic relativistic electron (URE) precipitations are determined due to indirect electromagnetic method. Previously we determined the southern boundaries of these precipitations in the frames of the following supposition: the effect of a normal wave reflection and its conversion into other normal waves on the boundary between disturbed and undisturbed parts of a radio path might have been ignored. Now we show by accurate simulation that it was true for strong and moderate disturbances. For the powerful URE disturbances the effect is significant. In order to obtain this result we had to change a traditional problem statement about a normal wave conversion in the terrestrial waveguide and to solve numerically this new problem with a  ${}$  prime  $\$  prime  $\$  normal  ${}$  inhomogeneity.

# Estimation of the mode conversion effect on the determination of southern boundary for the $\sim 100$ MeV electron precipitations

#### 12 Abstract

The parameters of sporadic  $D_s$  layer of electric conductivity caused by ultraenergetic rel-13 ativistic electron (URE) precipitations are determined due to indirect electromagnetic 14 method. Previously we determined the southern boundaries of these precipitations in 15 the frames of the following supposition: the effect of a normal wave reflection and its con-16 version into other normal waves on the boundary between disturbed and undisturbed 17 parts of a radio path might have been ignored. Now we show by accurate simulation that 18 it was true for strong and moderate disturbances. For the powerful URE disturbances 19 the effect is significant. In order to obtain this result we had to change a traditional prob-20 lem statement about a normal wave conversion in the terrestrial waveguide and to solve 21 numerically this new problem with a "volume" inhomogeneity. 22

#### 23 1 Introduction

A phenomenon of ultraenergetic relativistic electron (URE) precipitation with ab-24 normally high intensity into polar atmosphere was stated by the help of indirect very low 25 frequency (VLF)-method (*Remenets and Beloglazov*(1985), Remenets and Beloglazov(1985); 26 Remenets and Beloglazov(2013), Remenets and Beloglazov(2013)) more than 30 years 27 ago. During these years the monitoring of the fluxes of  $\sim 100 \text{ MeV}$  electrons in the near 28 cosmos did not appear although the fluxes of highly-energetic relativistic electrons (HRE) 20 with energy from  $\sim 1$  to  $\sim 10$  MeV were measured about the same 30 years (*Callis et* 30 al.(1991), Callis et al.(1991); Pesnell et al.(1999), Pesnell et al.(1999)) and the fluxes of 31 GeV electrons were monitored more than 10 years (Andriani et al. (2017), Andriani et 32 al.(2017)). The window (gap) between these measurements was partially overlapped by 33 the ground VLF measurements, which we have indicated above. 34

The VLF waves generated by a ground based transmitter and propagating in a 35 terrestrial waveguide between two conducting mediums (which are the ground and bot-36 tom ionosphere) are sensitive to the time dependence of electric conductivity of this bot-37 tom and to its dynamics being caused either due to the ionization of neutrals by the pre-38 cipitating electrons or by hard electromagnetic radiation. At the same time the ultraenergetic relativistic electrons (URE/s) are the sources of very significant bremsstrahlung 40 radiation in the atmosphere (Satio Hayakawa(1969), Satio Hayakawa(1969); Remenets 41 and Beloglazov(2013), Remenets and Beloglazov(2013)) if the density of corpuscular flux 42 is abnormally high (*Remenets and Beloglazov*(2013), Remenets and Beloglazov(2013)). 43

It is known that the electrons with energy  $\sim 100$  MeV do not penetrate mainly 44 into the atmosphere deeper than the altitude with the pressure  $50q/cm^2$ , that is, deeper 45  $\sim 40$  km. Therefore, significant electric conductivity, registered by VLF-method at the 46 altitudes 30 km and lower (Beloglazov and Remenets(2005), Beloglazov and Remenets(2005)) 47 can be caused only by the bremsstrahlung X- and gamma rays. These rays created a spo-48 radic  $D_s$  - layer, which manifesed itself in both existing numerical solutions of the in-49 verse VLF problem (*Remenets*(1997), Remenets(1997); *Beloglazov and Remenets*(2005), 50 Beloglazov and Remenets (2005); Remenets and Beloglazov (2013), Remenets and Beloglazov (2013)). 51 The pointed solutions were based on a theory of VLF wave propagation in near-Earth 52 wave guide, that is, they were based on the Maxwell's equation consequences for a physics 53 model of waveguide (?, ?; Makarov et al. (1993), Makarov et al. (1993)). One of the pointed 54 solutions of the inverse problem uses the ray ("hop") theory (using the Watson-Fock diffrac-55 tion wave and two rays reflecting from a "bottom" of atmosphere ionized) (*Remenets*(1997), 56 Remenets(1997): Bondarenko and Remenets(2001). Bondarenko and Remenets(2001); 57 Remenets and Beloglazov(2013), Remenets and Beloglazov(2013); Remenets and Astafiev(2015), 58 Remenets and Astafiev(2015); Remenets and Astafiev(2016), Remenets and Astafiev(2016)), 59 and the other version of inverse problem uses the normal waves (modes) in the waveg-60 uide (Remenets(1994), Remenets(1994); Remenets(1997), Remenets(1997); Beloglazov 61 et al. (1998), Beloglazov et al. (1998); Beloglazov and Remenets (2005), Beloglazov and 62 Remenets(2005)). Both types of solutions complement each other and give practically 63

the same values of effective heights (*Remenets*(1997), Remenets(1997); *Beloglazov and Remenets*(2005), Beloglazov and Remenets(2005)).

In order to model the  $D_s$ -layer conductivity as function of altitude z we used in 66 the last pointed works an approximation of its profile with two free parameters – the thick-67 ness  $z_1 \div z_0$  of its homogeneous conductivity and the gradient  $\beta$  of its exponential de-68 pendence at altitudes below  $z_1$ , Figure 1. The upper part of ionosphere higher than  $z_0 \sim$ 69 60 km was considered undisturbed by the URE precipitations, and was approximated 70 by exponential dependence on z for an electron concentration profile  $N_e(z)$  (Beloglazov 71 and Zabavina(1982a), Beloglazov and Zabavina(1982a); Beloglazov and Zabavina(1982b), 72 Beloglazov and Zabavina(1982b)). The logarithm of schematic  $\sigma$  function (a dotted curve 73 with number 4 for Figure 1.) has two "elbows" at altitudes  $z_0$  and  $z_1$ . With such type 74 of approximation for a sporadic  $D_s$ -layer the inverse problems were solved. The output 75 parameters of the solution were the  $z_1$  and  $\beta$ , and their values are represented for sev-76 eral time moments of the URE precipitations on 29 September 1989, 21 and 22 January 77 2002, the Table 1 and Table 2, which are reproduced from the works (*Remenets*(1997), 78 Remenets(1997); Beloglazov and Remenets(2005), Beloglazov and Remenets(2005)). 79

The approximation parameters,  $z_1$  and  $\beta$  for profile  $N_e(z)$  (with the profile of 80 effective electron collisions having been fixed), were found due to the procedure of min-81 imization of a discrepancy-function for 3 frequencies between the experimental and cal-82 culated amplitude and phase variations of signals caused by an URE precipitation. It 83 is necessary to note that when one tries to satisfy the experimental VLF data (ampli-84 tude and phase variations for 3 frequencies) for the auroral radio path  $S_1$  (Aldra-Apatity) with length  $\sim 900$  km (in the cases of UREP disturbances) with the help of monotonous 86 exponential electron concentration profile  $N_e(z)$  it turns out that it is impossible to do 87 it correctly (reliably): the amplitude data demand for themselves an  $N_e(z)$  with its ef-88 fective height at 20 km lower than the effective height of an electron concentration pro-89 file suitable for the phase data. It was possible to overpass this contradiction only by an 90 adoption that for satisfying the amplitude and phase data simultaneously it was neces-91 sary to use not monotonic *effective* profile  $N_e$ , the corresponding profile of electric con-92 ductivity having been monotonic. This qualitative discrepancy between the  $\sigma(z)$  and  $N_e(z)$ 93 profiles is caused by the item that electric conductivity below 50 km is determined by 94 the electrons and ions, so  $N_e(z)$  is a profile of the effective electron concentration. 95

<sup>96</sup> Now we return to the Table 1 and Table 2 for which a comparison of experimen-<sup>97</sup> tal and theoretical magnitude values is represented. The profile of electron collision fre-<sup>98</sup> quency (with the atoms of air) was accepted for these calculations as it follows:  $\nu_{eff} =$ <sup>99</sup> 0.87 10<sup>7</sup> exp b(z - 70km) 1/s with b = -0.14 1/km. Theoretical values of field mag-<sup>100</sup> nitudes (the digits in the brackets) were calculated using the values  $z_1$  and  $\beta$  for the  $\sigma$ -<sup>101</sup> profile with the number 4 kind, Figure 1. The description of the table parameters and <sup>102</sup> magnitudes is the following:

an index j = 1, 2, 3 is the number of frequency used in the experiment (10.2, 12.1, 13.6 kHz correspondingly);

 $(A_j)_c$  – a value of amplitude in undisturbed (calm) conditions;  $(A_j)_d$  – a value of disturbed amplitude at UT moment pointed in first lines of the Tables 1 and 2;

 $(\varphi_j)_c$  – a value of phase in undisturbed conditions;  $(\varphi_j)_d$  – a value of disturbed phase at UT moment pointed in first line.

The pointed magnitudes (without brackets) are the input ones for an inverse problem. The other parameters of the tables below the amplitude and phase data are the output magnitudes:

<sup>112</sup>  $z_1$  and  $\beta$ ; h' – an effective height of a waveguide with a nonmonotonic  $N_e(z)$  pro-<sup>113</sup> file, acquired by using the amplitude and phase data (6 magnitudes); h'' – an effective <sup>114</sup> height of a waveguide with a nonmonotonic  $N_e(z)$ -profile, gotten by using phase data <sup>115</sup> (3 magnitudes); h''' – an effective height of a waveguide with a nonmonotonic  $N_e(z)$ -profile, <sup>116</sup> gotten by using phase data (3 magnitudes); h – an effective height of a waveguide, got-<sup>117</sup> ten for the same time moments by another VLF inverse problem solution (*Remenets and* <sup>118</sup> *Beloglazov*(1985), Remenets and Beloglazov(1985); *Remenets and Beloglazov*(1992), Remenets and Beloglazov(1992)); this method is a self-consistent one, that is, it does not need the input geophysical data, and is based on the experimental VLF data and the theory of wave propagation completely.

Concluding the discussion of the Table 1 and Table 2 we ought to point out that 122 the effective heights with primes for a given  $N_e(z)$ -profile were calculated by a special 123 procedure (Galyuk and Ivanov (1978), Galyuk and Ivanov (1978); Remenets and Bel-124 oglazov(2013), Remenets and Beloglazov(2013); Remenets and Astafiev(2019), Remenets 125 and Astafiev(2019)): 1-st step – the value of an impedance function is calculated for any 126 altitude at which the electric conductivity is negligible by integration of not linear equa-127 tion for impedance function from  $z_2$  top to down; 2-d step – the gotten value is used as 128 the initial value for integration of the impedance function equation for empty medium 129 in opposite direction until a height h' for which the impedance function becomes real (Galyuk 130 and Ivanov (1978), Galyuk and Ivanov (1978)). Such acquired height is called an effec-131 tive one due to the statement that the phase path of a propagating mode in the real ter-132 restrial waveguide is the same as in a model air waveguide with h' height. Therefore, the 133 tables represented and described is a part of electromagnetic proof of sporadic  $D_s$ -layer 134 existence. Now we pass to new calculation problem. 135

According to the  $z_1$  values of Table 1 (which is for daytime conditions) it can be seen that these values differ negligibly from  $z_0$ . Therefore, we use below an approximation with one parameter – gradient  $\beta$ , and  $z_1 \equiv z_0$  being adopted (*Bondarenko and Remenets*(2001), Bondarenko and Remenets(2001)). Therefore, we use at present publication one "elbow" approximation of the  $D_s$ -layer, the curves 1 - 3 for Figure 1.

#### <sup>141</sup> 2 Physical and mathematical problems

In our works (Remenets and Astafiev (2015), Remenets and Astafiev (2015); Remenets 142 and Astafiev(2016), Remenets and Astafiev(2016)) we have determined the southern bound-143 aries of URE precipitations which had been registered (about 300 events during 1982) 144 1992 years) by a VLF-method. The method was based on continuous ground-based mea-145 surements (by the scientists of the Polar Geophysical Institute – RAS, Apatity, Murmansk 146 reg., Russia) of amplitude and phase disturbances for several VLF-signals for two radio 147 paths: one path  $S_1$  was completely auroral and the second path  $S_2$  (United Kingdom 148 - Kola Peninsula) was partly auroral. The part of the atmosphere which is higher than 149 61° of magnetic latitude is electrically disturbed during an URE precipitation (UREP). 150 This boundary is higher at several degrees than the analog boundary for the protons with 151 energy 0.1 - 0.4 GeV, figure 39 of the work (Andriani et al.(2017), Andriani et al.(2017)). 152 Due to an URE precipitation the profile of electric conductivity is changing below a cer-153 tain altitude  $(z_0)$ , under a regular ionosphere D-layer a sporadic  $D_s$ -layer appears caused 154 by the bremsstrahlung X-ray radiation which is generated by the precipitating electrons. 155 Therefore, the radio path  $S_2$  becomes significantly inhomogeneous along its length. The 156 breaking of radio path homogeneity we model by an abrupt hop of electric properties 157 at a distance D from a receiver, and the properties for both sides from this boundary are 158 being homogeneous along the path but different. The pointed inhomogeneity of radio 159 path is the cause of conversion of a normal wave of terrestrial wave guide at other nor-160 mal waves. Having a certain quantitative estimations about a significance of this effect 161 on the base of our predecessor calculations for other types of inhomogeneity (such as an 162 abrupt change of electric properties of ground, an abrupt change of waveguide effective 163 height) (Bahar and Wait (1965), Bahar and Wait (1965); Wait (1968), Wait (1968); Wait 164 and Spies(1968), Wait and Spies(1968); Pappert and Morfitt(1972), Pappert and Mor-165 fitt(1972); Smith(1977), Smith(1977); Osadchiy and Remenets(1979), Osadchiy and Remenets(1979); 166 Pappert and Ferguson (1986), Pappert and Ferguson (1986)) we ignored the pointed ef-167 fect in the publications (*Remenets and Astafiev*(2015)), Remenets and Astafiev(2015); 168 Remenets and Astafiev (2016), Remenets and Astafiev (2016)). Nevertheless, here we have 169 to justify our previous neglect by taking into account the effect of conversion of a nor-170 mal wave in other ones and to point for what type of UREP (moderate, strong or pow-171

erful) it is necessary to take into account this effect while a boundary latitude calcula-172

tion. For this purpose we would to change the traditional problem statement. 173

Let us give short comments of the works devoted to the mode conversion in a 174 terrestrial waveguide taking into account that the anisotropic properties of low ionosphere 175 are absolutely negligible for us due to the analysis here only the daytime disturbances. 176 For them the effective height h of a waveguide is falling down from 60 to 50, 40 and even 177 30 km during the UREPs. One ought to take into account that this height is always present 178 inside the altitude part of ionosphere which determines a mode reflection to ground. Among 179 the works of pointed type Bahar and Wait(1965) (Bahar and Wait(1965)); Wait(1968)180 (Wait (1968)); Wait and Spies (1968) (Wait and Spies (1968)) there are the following ones: 181 a work, in which an abrupt change of top waveguide boundary with given impedance is 182 introduced, the works with the models of the day-night transition in a VLF waveguide, 183 and cylindrical model of the wave guide instead of spherical one being used. This type 184 of model does not suit us because of the following issues: 185

1) the eigenfunctions of day-side do not orthogonal in the night-side section and vice versa due to the different widths of the left and right sections, therefore this item generates an uncontrolled error:

186

187

188

197

2) the named eigenfunctions are accurately orthogonal only if the impedance of a 189 waveguide top boundary is constant, that is, the impedance does not depend on the eigen-190 value. But the last item works sufficiently good only at high altitudes where the elec-191 tric conductivity is sufficiently high, and this item works badly if the bottom boundary 192 is chosen for an altitude where the electric conductivity is low. 193

3) In the works (*Pappert and Morfitt*(1972), Pappert and Morfitt(1972); *Pappert* 194 and Ferguson(1986), Pappert and Ferguson(1986)) the plain waveguide model was used. 195 This type of modeling does not suit us too, because the height gain functions for a plain 196 waveguide and a spherical waveguide are significantly different for relatively high frequencies. 198

4) In the work (Galeis(1964), Galeis(1964)) the author used the plain model too 199 taking into account the sphericity effect either by a certain approximation or using a cylin-200 drical waveguide (Galejs(1968), Galejs(1968); Galejs(1969), Galejs(1969)) according to 201 J. R. Wait (*Wait*(1964), Wait(1964)). 202

The pointed mathematical differences are relatively subtle notions, but it is nec-203 essary to pay main attention that in all mentioned works the heterogeneities were lat-204 eral (sidelong) ones: either an abrupt change of the boundary surface impedance or a 205 change of the height of an empty waveguide (modeling of a transition from day to night) 206 . Therefore, it is necessary *in our case* to make another statement of problem about the 207 normal waves conversion on an abrupt radial change of the medium properties without artificial and weakly controlled dividing the transverse conducting medium at two fol-209 lowing parts: the bottom part which is empty medium (vacuum) and the top conduct-210 ing part which is not involved in the mode conversion calculations directly. 211

In our case the middle altitudes of the waveguide atmosphere are disturbed due 212 to an appearance of a  $D_s$ -layer. Therefore, we work with a transverse radial inhomogene-213 ity which is homogeneous along a disturbed part of the radio path. The problem with 214 such "volume" inhomogeneity will be solved in this paper. To-day, when the simulation 215 possibilities are much greater than 50-60 years ago it is not necessary to pass from spher-216 ical geometry to the cylindrical or plane ones for simplicity's sake. We have not met any 217 218 rigorous analog solution relative to our representation here except the cases when the quasi-optic approximations may be used as in the fiber optics analysis. 219

Therefore, we are solving a problem about the effect of normal wave conversion due 220 to an abrupt discontinuity of the transverse electric properties of a terrestrial waveguide 221 in the following model. The ideal spherical model of the Earth with homogeneous elec-222 tric properties and with its radius R = 6370 km is surrounded by two segments of isotropic 223 ionosphere each of which is determined by its profile of electron concentration  $N_e^{I,II}(r)$ 224 and a mutual profile of electron collision frequency with neutrals  $\nu_{eff}(r)$ . These profiles 225 determine the profiles of electric conductivity  $\sigma^{I}(r)$  or  $\sigma^{I}I(r)$  for the VLF wave prop-226

<sup>227</sup> agation. The first inner cone segment containing on its axis a source of the normal ra-<sup>228</sup> dio waves (a transmitter) is a frustum (truncated cone) bounded at its bottom by ground <sup>229</sup> with the impedance boundary conditions for it. The frustum is characterized by a value <sup>230</sup> of angle  $\theta_{irr}$  in the spherical coordinate system r,  $\theta$ ,  $\varphi$  (with its beginning in the cen-<sup>231</sup> ter of Earth ), and by a distance from a ground based source to the boundary along the <sup>232</sup> ground surface which is equal to  $R\theta_{irr}$ . The second space section is the space charac-<sup>233</sup> terized by  $\theta > \theta_{irr}$ .

Our purpose is to determine the reflection coefficient and conversion coefficients for a given normal wave penetrating through the boundary of abrupt medium changing at  $\theta = \theta_{irr}$ . The inner cone is characterized by undisturbed ionosphere of middle latitudes, and the outer sector is characterized by the ionosphere disturbed by an URE precipitation.

The waveguide properties are determined by a profile of electric conductivity which is increasing exponentially at radial infinity:  $\sigma(x) = Im(\varepsilon'(x))\omega$ ,

241 242 
$$\begin{split} k &= \omega \sqrt{\varepsilon' \mu_0} = \omega \sqrt{\varepsilon'_m \varepsilon_0 \mu_0} = k_0 \sqrt{\varepsilon'_m},\\ \varepsilon_m'(x) &= 1 - \frac{X(x)}{1 + jZ(x)}, \ X(x) = \frac{\omega_p^2(x)}{\omega^2}, \ Z(x) = \frac{\nu_{eff}(x)}{\omega}, \text{ where } j = \sqrt{-1}, \ \omega_p(x) - the \text{ plasma frequency}, \ x &= k_0 r \text{ is the dimensionless radial coordinate; } r - \text{ radial coord$$

243 dinate in the spherical coordinate system with the center in the Earth's center and the 244 polar axis passing through a VLF transmitter (in the United Kingdom, GBR-station in 245 Rugby); R – is the Earth's radius;  $k_0$  is a wave number for free space;  $\varepsilon' = \varepsilon'_m \cdot \varepsilon_0$ . The 246 electric conductivity is approximated by two exponential functions for which its loga-247 rithm is a function with an "elbow" at the altitude  $z_0 = r_0 - R$ , (Beloglazov and Zabav-248 ina(1982a), Beloglazov and Zabavina(1982a); Beloglazov and Zabavina(1982b), Be-249 loglazov and Zabavina(1982b)). This approximation corresponds to the auroral undis-250 turbed or moderately disturbed low ionosphere, Figure 1 with the curve 1 for  $\sigma^{I}(z)$ , where 251 z is an altitude. At a certain distance from the transmitter  $(S_2 - D, km)$  a new profile 252 of effective electric conductivity which makes a model of sporadic  $D_s$ -layer (for a cer-253 tain time of disturbance) with the help of significantly other elbow function: either  $\sigma_{str}^{II}(z)$ 254 - curve 2 or  $\sigma_{pow}^{II}(z)$  - curve 3 (Bondarenko and Remenets(2001), Bondarenko and Remenets(2001)), 255 see Figure 1. Due to the pointed models of conductivity profiles the normal waves ex-256 ist and penetrate until altitude  $z_2$  at which the impedance boundary conditions are used. 257 Therefore, we come to a problem of mode conversion at a transverse boundary of two 258 spherical jointed waveguides with equal width  $z_2$  and sufficiently accurate impedance bound-259 ary conditions at the bottom and top waveguide boundaries. 260

This statement of the simulation problem may seem to be fare away from the 261 real situation because: i) in reality there is a second axis of symmetry connected with the geomagnetic field, which determines a circular zone of very energetic solar proton 263 (100 MeV) (Dmitriev et al.(2010), Dmitriev et al.(2010)) and URE precipitations (Remenets 264 and Astafiev(2015), Remenets and Astafiev(2015)). Therefore, a normal wave propa-265 gating from England to Kola Peninsula is falling on the boundary of irregularity not nor-266 mally, see figure 1 in (*Remenets and Astafiev*(2016), Remenets and Astafiev(2016)). 267 ii) The real radius of boundary curvature is centered at the South magnetic pole, the cen-268 ter of model cone boundary is placed in England and its radius on earth has value  $R\theta_{irr} \simeq$ 269 2000 km. The first item we ignore because our purpose is to get an estimate of the ef-270 fect. The second item is insignificant for the problem because the propagation of the elec-271 tromagnetic waves is characterized by a local principle, which is formulated with the help 272 of the Fresnels zones which are plotted on the base of the transmitter and receiver points 273 in space which are the focuses of the ellipses enveloping the points. The width of a zone 274 is about square root of a product  $S_2 \lambda \simeq 200$  km, where the first multiplier is the dis-275 tance between the source in England and the receiver on the Kola Peninsula, and  $\lambda$  is 276 a wavelength for 16 kHz. 277

New computational problem is as follows. In the first cone section of the spherical model a  $TM_0$  normal wave with a given complex amplitude propagates from the transmitter to the waveguide joint which is described above. It is necessary to find the com-

plex amplitudes of the wave  $TM_0$  penetrated, the complex amplitudes of other normal 281 waves in the second cone section propagating from the junction boundary and the am-282 plitudes of normal waves generated at the boundary of two mediums and propagating 283 to the transmitter. In order to calculate them it is necessary to demand the continuity 284 of complex  $E_r$  and  $H_{\varphi}$  components at the cone boundary. The radial parts of normal 285 waves of a fixed cone section are orthogonal to each other in the complex Hilbert space 286 and this property is sufficient for answering the main question of the investigation: is 287 it necessary to take into consideration the conversion of the normal waves when one de-288 termines the southern boundary of URE precipitation? 289

### Components of electromagnetic waves in the inhomogeneous electrically conducting medium with the central symmetry

The complex amplitudes  $\vec{E}$  and  $\vec{H}$  of the electromagnetic field in the inhomogeneous electrically conducting medium with the central symmetry satisfy the Maxwell's equations for the time dependence of a source signal and the fields excepted in the form  $exp(-j\omega t)$ :

$$rot\vec{E} = j\omega\mu_0\vec{H},$$

296 (1)

$$rot \overrightarrow{H} = -j\omega \varepsilon' \overrightarrow{E}$$

$$\overrightarrow{H} = -j\omega rot \overrightarrow{\Pi}$$

299 (3)

$$\overrightarrow{E} = \frac{1}{\varepsilon'} rot(rot \overrightarrow{\Pi}),$$

 $\begin{array}{ll} {}_{300} & (4) \\ {}_{301} & \text{if the vector } \overrightarrow{\Pi} \text{ satisfies to the equation} \end{array}$ 

$$rot\{\frac{1}{\varepsilon'}rot(rot\overrightarrow{\Pi})\} - \omega^2\mu_0rot\overrightarrow{\Pi} = 0,$$

302 (5)

which may be transformed to the following:

$$rot(rot\vec{\Pi}) - k^2\vec{\Pi} - k^2\Phi = 0$$

303 (6),

where  $k(r) = \omega \epsilon'(r)\mu_0 = k_0 \varepsilon'_m(r)$ ;  $\varepsilon'_m(r) = \varepsilon'(r)/\varepsilon_0$ , and  $\Phi$  is an any smooth function. The magnitude  $\varepsilon'_m(r)$  is characterized here by the central symmetry. In this case the Herz vector has only one component  $\Pi_r$  which satisfies to the following equation

$$\frac{1}{r^{2}\sin\theta}\left[\frac{d}{d\theta}(\sin\theta\frac{d\Pi_{r}}{d\theta})\right] + \varepsilon_{m}^{'}\frac{d}{dr}\left(\frac{1}{\varepsilon_{m}^{'}}\frac{d\Pi_{r}}{dr}\right) + \varepsilon_{m}^{'}k_{0}^{2}\Pi_{r} = 0,$$

304 (7)

and the transverse components of the electromagnetic field are expressed by thefollowing relations:

$$H_{\varphi} = \frac{j\omega}{r} \frac{d\Pi_r}{d\theta},$$

307 (8)

$$E_r = \frac{1}{\varepsilon'} (\varepsilon'_m \frac{d}{dr} (\frac{1}{\varepsilon'_m} \frac{d\Pi_r}{dr}) + \varepsilon'_m k_0^2 \Pi_r).$$

308 (9)

Correspondingly, the component  $E_r$  is expressed with the help of the  $H_{\varphi}$  component:

$$E_r = \frac{i}{\varepsilon' r \omega \sin \theta} \cdot \frac{\partial (\sin \theta \cdot H_{\varphi})}{\partial \theta}.$$

309 (10)

According to the Maxwell equations (1) and (2) the equation for the  $H_{\varphi}$  component is gotten:

$$rot[\frac{1}{\varepsilon'}rotH_{\varphi}] = k_0^2 \varepsilon'_m H_{\varphi}$$

310 , (11) 311 that is,

$$\frac{1}{r^2} \cdot \frac{d}{d\theta} \left(\frac{1}{\sin \theta} \cdot \frac{d(\sin \theta \cdot H_{\varphi})}{d\theta}\right) + \frac{\varepsilon_m^{'}}{r} \frac{d}{dr} \left(\frac{1}{\varepsilon_m^{'}} \frac{d(r \cdot H_{\varphi})}{dr}\right) + \varepsilon_m^{'} k_0^2 H_{\varphi} = 0.$$

312 (12)

The equation (7) may be represented as a sum of the angular and radial differential operations relative to the  $\Pi_{r,\theta}$ :  $L_{\theta}\Pi_r + L_r\Pi_r = 0$ , where

$$L_{\theta} = \frac{1}{\sin \theta} \left[ \frac{d}{d\theta} (\sin \theta \frac{d}{d\theta}) \right],$$

(13)

$$L_r = r^2 \varepsilon_m^{'} \frac{d}{dr} (\frac{1}{\varepsilon_m^{'}} \frac{d}{dr}) + r^2 \varepsilon_m^{'} k_0^2.$$

313 (14)

The eigenvalues  $\lambda_n$  of the radial operator  $L_r$ , which is defined on the set of functions, which attenuate in the conducting plasma medium against the altitude and satisfy to the impedance boundary conditions on the ground surface, are defined by the following equality:

$$L_r \Pi_r = \lambda_n \Pi_r,$$

and as it is  $\Pi_r(r,\theta) = U(r) \cdot P(\theta)$  then:

$$L_r U(r) = \lambda_n U(r).$$

318 (15)

The last equation is transformed into the differential Ricatty equation (17) of first degree if to introduce the impedance function:

$$u(r) = \frac{\frac{dU(r)}{dr}}{\varepsilon'_m(r) \cdot U(r)}$$

319 (16)

Then

$$\frac{du(r)}{dr} + \varepsilon_m'(r) \cdot u(r)^2 = -k_0^2 + \frac{\lambda}{\varepsilon_m'(r) \cdot r^2}.$$

320 (17)

An eigenvalue  $\lambda_n$  is connected with the index of cylindrical functions in the cases of homogeneous medium with  $\varepsilon_m = 1$  by the following relation:  $\lambda_n = \nu_n^2 - 1/4$ . The same parameter  $\nu_n$  defines the asymptotic angular dependence of the field as follows:  $P(\theta) \sim \exp(j\nu_n\theta)$ ).

Inclusion of the computer integration of this Ricatty equation (17) from a top waveguide boundary to the ground (for which the impedance boundary conditions are given to us) into an iteration process relatively to the  $\nu$  produces an eigenvalue  $\nu_n$  and corresponding eigenfunction  $U(r, \nu_n)$  according to the (15). According to the (9) the following relation has place for an eigenfunction with number n:

$$E_{r,n} = \frac{1}{\varepsilon'_m(r) \cdot r^2} L_r \Pi_n(r,\theta) \simeq \frac{1}{\varepsilon'_m(r) \cdot r^2} \nu_n^2 \Pi_n(r,\theta) = \frac{1}{\varepsilon'_m(r) \cdot r^2} \nu_n^2 U_n(r) P_n(\theta).$$

330 (18)

According to the same relation (17) and to the asymptotic relation  $P_n(\theta) \sim \exp(j\nu_n\theta)$ one gets the value of the singular magnetic component of the  $TM_n$  normal wave with number *n*:

$$H_{\varphi,n} = \frac{j\omega}{r} \cdot \frac{d\Pi_{r,n}(r,\theta)}{d\theta} = \frac{j\omega}{r} \cdot U_n(r) \cdot \frac{dP_n(\theta)}{d\theta} = -\nu_n \frac{\omega}{r} \cdot U_n(r) \cdot P_n(\theta).$$

## 4 The system of equations generated by the demand of continuity of the transverse components of the TM electromagnetic field on the cone boundary of two mediums with different radial properties

According to the electromagnetic law the transverse components  $E_r$  (18) and  $H_{\varphi}$ 338 (19) must be continuous on the boundary surface of two different mediums, that is on 339 the truncated cone with  $\theta_{irr} = (S_2 - D)/R$  in our case. In the following we shall con-340 sider the conversion of one normal wave, n=1, into other ones. This normal wave (which 341 according to maknovryb93 is  $TM_0$  normal wave) with a given amplitude is propagating 342 from the cone with index I into to the outer medium with index II. The radial func-343 tion  $U_1(r)$  of its complex amplitude  $E_r$  is normalized to value 1 on spherical ground sur-344 face boundary  $(x = k_0 R, R)$  is the radius of Earth) inside the cone. In this cone the elec-345 tromagnetic field is the sum of the falling wave  $(E_1, H_1)$ , reflected wave  $(\mathbf{R}_1 E_{-1}, \mathbf{R}_1 H_{-1})$  and the sums of excited normal waves with numbers n > 1:  $\sum_{2}^{M} \mathbf{R}_n E_{-n}$ ,  $\sum_{2}^{M} \mathbf{R}_n H_{-n}$ . 346 347 Then 348

351

352

3

$$E_I = E_1 + \sum_{n=2}^{M} \mathbf{R}_n E_{-n}, \quad H_I = H_1 + \sum_{n=2}^{M} \mathbf{R}_n H_{-n}.$$
 (20)

In the outer medium with number (II) the field is the sum of the excited normal waves which are propagating from the boundary:

(21)

$$E_{II} = \sum_{n=1}^{M} \mathbf{T}_n E_n, \quad H_{II} = \sum_{n=1}^{M} \mathbf{T}_n H_n$$

where the component indexes r and  $\varphi$  are omitted, and  $T_n$  are the complex amplitudes of the passed wave with number n = 1 and the excited ones. Demanding the continuity of the full field components on the transverse boundary and taking into consideration that  $\nu_n$  for a wave propagating in positive direction differs from the wave propagating in opposite direction by a sign  $(\nu_{-n} = -\nu_n)$  we have the following relations for the radial eigenfunctions and the conversion coefficients on the cone boundary:

$$\sum_{i=1}^{59} \frac{\nu_{1}^{I2}}{\varepsilon_{m,I}(x)} U_{1}^{I}(x) + \sum_{n=1}^{M} \operatorname{R}_{n} \frac{\nu_{n}^{I2}}{\varepsilon_{m,I}(x)} U_{n}^{I}(x) = \sum_{n=1}^{M} \operatorname{T}_{n} \frac{\nu_{n}^{I12}}{\varepsilon_{m,II}(x)} U_{n}^{II}(x), \qquad (22)$$

$$\nu_{1}^{I} \cdot U_{1}^{I}(x) - \sum_{n=1}^{M} \nu_{n}^{I} \cdot \operatorname{R}_{n} U_{n}^{I}(x) = \sum_{n=1}^{M} \nu_{n}^{II} \cdot \operatorname{T}_{n} U_{n}^{II}(x), \qquad (23)$$

where the integer M is used instead of infinite value. For a value choice M = 3the equality (23) for full  $H_{\varphi}$  component and the equality (22) for full  $E_r$  component may be rewritten in the form (24) and (25) correspondingly:

$$\nu_{1}^{I} \left[ U_{1}^{I}(x) - R_{1} U_{1}^{I}(x) - \frac{\nu_{2}^{I}}{\nu_{1}^{I}} R_{2} U_{2}^{I}(x) - \frac{\nu_{3}^{I}}{\nu_{1}^{I}} R_{3} U_{3}^{I}(x) \right]$$
  
=  $\nu_{1}^{II} \left[ T_{1} U_{1}^{II}(x) + \frac{\nu_{2}^{II}}{\nu_{1}^{II}} T_{2} U_{2}^{II}(x) + \frac{\nu_{3}^{II}}{\nu_{1}^{II}} T_{3} U_{3}^{II}(x) \right],$ 

(24)364

$$\frac{1}{\varepsilon_m^I(x)} \left[ (\nu_1^I)^2 U_1^I(x) + R_1 (\nu_1^I)^2 U_1^I(x) + R_2 (\nu_2^I)^2 U_2^I(x) + R_3 (\nu_3^I)^2 U_3^I(x) \right] = \frac{1}{\varepsilon_m^{II}(x)} \left[ T_1 (\nu_1^{II})^2 U_1^{II}(x) + T_2 (\nu_2^{II})^2 U_2^{II}(x) + T_3 (\nu_3^{II})^2 U_3^{II}(x) \right]$$

(25)365

#### 5 Determination of the mode conversion coefficients 366

By multiplying consequently these last equalities by the eigenfunctions of the not 367 self-adjoint operator of conjugate boundary problem for 2-nd section and by calculat-368 ing the scalar products according their definition for a not self-adjoint operator (*Titchmarsh*(1946), 369 Titchmarsh(1946); Keldysh (1951), Keldysh (1951); Wait(1964), Wait(1964); ?, ?; Makarov 370 and Novikov(1968), Makarov and Novikov(1968); Krasnushkin and Baibulatov(1968), Kras-371 nushkin and Baibulatov(1968); Krasnushkin(1969), Krasnushkin(1969); Pappert and Smith(1972), Pappert and Smith(1972))  $\langle U_n * U_m \rangle \equiv \int_{x=k_0R}^{x=k_0(R+z_2)} U_n(x)U_m(x)dx$ , which is not equal to zero for n = m, one gets the following 6 algebraic relations corresponding to 372 373 374 37

$$_{5}$$
 3 normal waves, used in our numerical calculations,  $n = 1, 2, 3$ :

$$\begin{split} \nu_1^I &< U_1^I(x) * U_i^{II}(x) > - \\ &- R_1 \, \nu_1^I \, < U_1^I(x) * U_i^{II}(x) > - \\ &- R_2 \, \nu_2^I \, < U_2^I(x) * U_i^{II}(x) > - \\ &- R_3 \, \nu_3^I \, < U_3^I(x) * U_i^{II}(x) > = \\ &= T_i \, \nu_i^{II} \, < U_i^{II}(x) * U_i^{II}(x) > \equiv T_i \, \nu_i^{II} \, N_i^{II}, \end{split}$$

376 (26)

$$\begin{split} (\nu_{1}^{I})^{2} &< \frac{\varepsilon_{m}^{II}(x)}{\varepsilon_{m}^{I}(x)} U_{1}^{I}(x) * U_{i}^{II}(x) > + \\ &+ R_{1} (\nu_{1}^{I})^{2} < \frac{\varepsilon_{m}^{II}(x)}{\varepsilon_{m}^{I}(x)} U_{1}^{I}(x) * U_{i}^{II}(x) > + \\ &+ R_{2} (\nu_{2}^{I})^{2} < \frac{\varepsilon_{m}^{II}(x)}{\varepsilon_{m}^{I}(x)} U_{2}^{I}(x) * U_{i}^{II}(x) > + \\ &+ R_{3} (\nu_{3}^{I})^{2} < \frac{\varepsilon_{m}^{II}(x)}{\varepsilon_{m}^{I}(x)} U_{3}^{I}(x) * U_{i}^{II}(x) > = \\ &= T_{i} (\nu_{i}^{II})^{2} < U_{i}^{II}(x) * U_{i}^{II}(x) > = T_{i} (\nu_{i}^{II})^{2} N_{i}^{II}, \end{split}$$

(27)377

where *i* is a number of the  $U_i^{II}(x)$  eigenfunction used for multiplication, and the  $N_i^{II}$  is its norm. We used the following normalization:  $U_i^{I,II}(r=R) = 1$ . 378 379

According to these 6 equation 3 reflection coefficients  $R_n^I$  and 3 transition coefficients  $T_n^{II}$  were determined for abrupt transition in the waveguide from  $\varepsilon_m^I(x)$  to  $\varepsilon_m^{II}(x)$ , for which  $\sigma^I$ ,  $(\sigma_{str}^{II})$  and  $(\sigma_{pow}^{II})$  of Figure 1 correspond. They are represented for Table 3.

The data of the lust column (the powerful disturbance (PwD)) of this table were used for getting the relative comparison of the altitude distributions of the terms of the sum at (24), and this comparison is represented for Figure 2. This comparison is approximately correct due to the fact that in our frequency case the first eigenvalues  $\nu_n$  differ from each other at 4-th – 3-d digits. Therefore, the Figure 2 gives the relative comparison of the complex altitude amplitude of the  $TM_0$  normal wave falling on the " volume" inhomogeneity, caused by an URE precipitation,

391 392

303

394

395

396

424

425

(i) with the amplitudes of the  $TM_0$  transmitted  $T_1U_1^{II}$  and reflected  $R_1U_1^{I}$ ,

(ii) with the  $TM_1$  generated by the boundary of inhomogeneity with one of its  $T_2U_2^{II}$  part propagating to a receiver and the other  $R_2U_2^{I}$  one of it propagating to the VLF source and

(iii) with the  $TM_2$  normal wave generated by the inhomogeneity with its  $T_3U_3^{II}$  part propagating to a receiver and the other  $R_3U_3^I$  one of it propagating to the VLF source.

The Table 3 and Figure 2 demonstrate that the conversion effect of  $TM_0$  normal wave into the  $TM_2$  normal wave (with number n = 3) is negligible relative to the errors of measurements, and, consequently, our analysis usage of only 3 normal waves is justified.

Therefore, according to the calculations represented we see that at the maximum 401 of a powerful VLF disturbance an effect of main normal wave  $TM_0$  transition  $(T_1 \cdot U_1^{II}(z))$ 402 for its amplitude on ground (z = 0) is  $\approx 15\%$  and for its phase is  $\approx 0.2$  rad. The last 403 value at 3 times greater than the phase measurement error in our case ( $1\mu s \sim 0.06 \ rad.$ 404 for our working frequency 16 kHz). At the same time we see (Table 3) that for a strong 405 VLF disturbance the calculated result for the main  $TM_0$  normal wave indicates on am-406 plitude decrees at 0.93 times for the maximum and the phase change at 1.2  $\mu$ s, id est., 407 at 0.07 rad. These changes of complex magnitude  $T_1$  are comparable with the measure-408 ment errors of the experimental data used by us remast15. More than that, as the de-409 termined boundary of URE precipitations is an analysis product of a full disturbance (which 410 is a function of time), then the mode conversion effect for the maximum of a disturbance 411 cannot be extrapolated for all stages of the disturbance. More than that, in the pointed 412 work we used only strong and moderate disturbances (StD and MdD ) 413

It seems that another normal wave  $TM_1$  with  $T_2 \cdot U_2^{II}(x)$  ought to be considered in analysis, but it is not so. The difference between the image parts of the eigenvalues for first two normal waves in the disturbed section is so great that the second one which is excited by the first normal wave  $TM_0$  at the inhomogeneity boundary does not achieve a receiver due the greater attenuation.

In addition to the pointed items one ought to consider that in reality there is non abrupt change of the boundary properties. In reality a relatively smooth change, with a space scale about 1 degree changing of electric properties, exists, and, therefore, the represented values of the mode conversion are the above estimations for the real ones. We state

(i) that existence of a sporadic  $D_s$ - layer of electric conductivity appearing under the regular ionosphere D-layer has an electromagnetic proof;

(ii) that in our procedure of southern boundary determination *Remenets and Astafiev*(2015)
(Remenets and Astafiev(2015)); *Remenets and Astafiev*(2016) (Remenets and Astafiev(2016))
in which only strong and moderate disturbances (StD's and MdD's) caused by the URE
precipitations were used the effect of normal wave conversion is negligible. In the case
of a powerful disturbance it is necessary to be careful in analysis.

At the same time we may state that in the cases of the most powerful proton precipitations (such as on 16 February 1984 and 29 September 1989) for which the effective height fell down to 50 and 45 km correspondently, *Remenets*(1997) (Remenets(1997)), one may expect the analog qualitative results. But they should be quantitatively weaker significantly due to the absence of bremsstrahlung X-rays and the corresponding spo radic D<sub>s</sub>-layer of the electric conductivity below the regular D-layer of the ionosphere.

In addition to the above quantitative results important for the effects connect-437 ing with the ultraenergetic relativistic electron ( $\sim 100 \text{ MeV}$ ) precipitations Remenets 438 and Astafiev(2015) (Remenets and Astafiev(2015)); Remenets and Astafiev(2016) (Remenets 439 and Astafiev(2016)): Remenets and Astafiev(2019) (Remenets and Astafiev(2019)) we 440 have demonstrated in present paper an efficiency of our not traditional stating of a prob-441 lem about mode (normal wave) conversion and obtaining its solution. Such type of prob-442 lems exists more than 50 years but only now it became possible to get the solution of 443 the problem in natural for spherical Earth model statement in which the space in trans-444 verse surface of a waveguide is not divided empirically on the air bottom part and elec-445 trically active top part. After such dismemberment the previous authors solved the prob-446 lem of mode conversion from one air part of waveguide to another air part, and the in-447 put into conversion of the upper electrically active and different parts being ignored. We 448 consider that in present work we have passed this point of discussion. We considered a 449 mode transition from one transversely inhomogeneous medium to another transversely 450 inhomogeneous medium with the corresponding quantitative results. We consider that 451 our suggested and used approach to the mode conversion will be useful in the waveguides 452 with natural or artificial transverse inhomogeneity the size of which is comparable with 453 the height of a waveguide. Such situation appears not only in the cases of ultraenergetic 454 relativistic electron precipitations coming from the Sun but in the astrophysics cases too 455 Tanaka et al. (2008) (Tanaka et al. (2008)), Tanaka et al. (2010) (Tanaka et al. (2010)). Very short (much less than one second) hard  $\gamma$  ray bursts from a certain space point illumi-457 nate the half of Earths atmosphere, create the corresponding  $D_s$  layer of electric con-458 ductivity in the middle and low atmosphere. The problem of transverse "volume" in-459 homogeneity boundary appears too. 460

Relative success of our analysis is due to the fact that the spectra of radial (transvers)
not self-adjoint operator for the problem of electromagnetic wave diffraction at a sphere
is discrete (*Fock*(1965), Fock(1965)). How to solve analytically a problem of reflection
of plain wave from an electrically inhomogeneous in one transverse dimension plane we
dont know.

Again we have right to remind that the ultraenergetic relativistic electrons being the cause of present investigation are the electron-killers with energy  $\sim 100$  MeV which ought to be much more dangerous than the traditional relativistic ones with energy  $\sim$ 1 - 10 Mev.

#### 470 Acknowledgments

471 As we explained in the Introduction, the present investigation is based on our previous

solutions of inverse VLF problem (*Remenets and Beloglazov*(1999), Remenets and Be-

- <sup>473</sup> loglazov(1999)), (*Beloglazov and Remenets*(2005), Beloglazov and Remenets(2005)).

Table 1. Results of the inverse VLF problem solutions for three UT moments for URE precipitation on 29 September 1989 gotten by using the normal wave theory of propagation. The computed values are given in brackets for comparison with the experimental ones. <sup>*a*</sup>

<sup>*a*</sup> The URE precipitation took a place at 0400 – 1000 UT interval. The values  $(A_j)_c$  and  $(\varphi_j)_c$  were referred to 0400 UT, rembel92.

Table 2. Results of the inverse VLF problem solutions for the UT moments of disturbance maximum for URE precipitation on 21 and 22 January 1992 gotten by using the normal wave theory of propagation, polar night conditions. The computed values are given in the brackets for comparison with the experimental ones.<sup>b</sup>

<sup>b</sup>The values of "knee" altitude  $z_0$  for the electron profile were taken equal to either 70 or 75 km in order to estimate the influence of its uncertainty on the  $z_1$  and  $\beta$  parameters of a sporadic  $D_s$ -layer.

Table 3. The values of complex reflection and transition coefficients  $R_j$  and  $T_j$  for two models of inhomogeneity junction: with the conductivity profiles  $\sigma_{str}^{II}(x)$  and  $\sigma_{pow}^{II}(x)$ , Fig. 1.<sup>c</sup>

$\begin{array}{c} \text{Sporadic} \\ D_s \\ \text{layer} \end{array}$	$\sigma^{II}_{str}(x)$	$\sigma_{pow}^{II}(x)$
$\begin{array}{c} R_1 \\ T_1 \end{array}$	- 0.0005 + j0.0008 + 0.9223 + i0.1095	- 0.001 + j0.003 + 0.839 + j0.188
$\begin{array}{c} R_2 \\ T_2 \end{array}$	+ 0.0010 - j0.0013 + 0.0872 - j0.1216	+ 0.004 - j0.005 + 0.179 - j0.174
$egin{array}{c} R_3 \ T_3 \end{array}$	- 0.0004 + j0.0006 - 0.0168 - j0.0150	- 0.001 + j0.001 - 0.019 - j0.006

 $^{c}$  The undisturbed conductivity profile was  $\sigma^{I},$  Fig. 1.

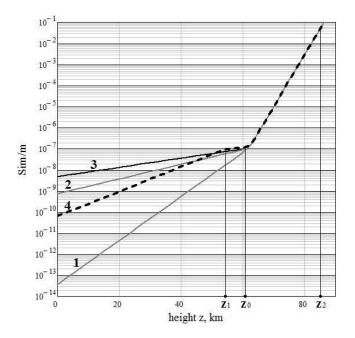

Figure 1. The effective profiles of electric conductivity for undisturbed ( $\sigma^{I}$  – curve 1) and disturbed ( $\sigma^{II}_{str}$  – curve 2,  $\sigma^{II}_{pow}$  – curve 3) conditions. The bottom indexes of electric conductivity "str" and "pow" correspond to the maximums of a strong and a powerful VLF disturbances bondrem01, belrem05. Undisturbed auroral profile  $\sigma^{I}$  was taken from the work belzab82a.

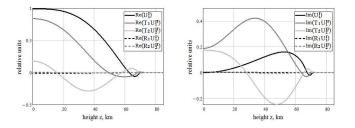

Figure 2. Comparison of the altitude distributions for the complex amplitudes of the converted normal waves in the waveguide by the longitudinal  $D_s$  heterogeneity. The source of excitation is a normal wave  $TM_0$  ( $U_1^I(x)$  normalized to 1 at  $x = k_0 R$ ) propagating to the cone boundary. The left and right parts of the panel are the real and image parts of the magnitudes.
