Abstract

Infection of urachal remnant may cause recurrent abscesses. In the current case report, we describe an urachal remnant infection leading to a retroperitoneal abscess, which is extremely rare condition. In such cases, the recommended treatment is urachal remnant resection.

Abstract

Infection of urachal remnant may cause recurrent abscesses. In the current case report, we describe an urachal remnant infection leading to a retroperitoneal abscess, which is extremely rare condition. In such cases, the recommended treatment is urachal remnant resection.

Keywords: retroperitoneal abscess, urachal remnant, ureteral resection

Case presentation

Abscess formation due to infection of urachal remnants is usually localized. A retroperitoneal abscess resulting from such infection is quite rare. [1] [2].

A 65-year-old man with fever and abdominal pain was admitted to our hospital.

Upon computed tomography (CT), we observed gas and extensive abscess formation in the preperitoneal space from the lower abdomen to the pelvis (Fig 1A). We performed emergency laparotomy. Laparoscopic examination of the abdominal cavity revealed no obvious perforation of the gastrointestinal tract and no obvious abscess formation; however, there was marked swelling of the abdominal wall centered on the midline

umbilical cord, suggesting abscess formation in the same area (Fig 1B). Through a midline incision in the lower abdomen, the Retzius cavity was opened and cleaned, and a drainage tube was placed. On follow-up at 4-6 months postoperatively, a recurrence of retroperitoneal abscess was observed. The patient underwent CT-guided drainage of this new abscess. CT contrast scan showed a slightly hyperdense cord-like structure extending from the umbilical region to the bladder, which was assumed to be a urachal remnant (Fig 1C). This led us to the conclusion that the abscess must have formed in this urachal remnant, subsequently spreading to the retroperitoneum. Hence, we decided to resect this urachal remnant. A laparoscopic ureteral remnant resection was performed. The median cord, i.e., the presumed urachal remnant, was detached from the abdominal wall (Fig 1D).
