## Abstract

*Bacillus* spp. strains that are beneficial to plants are widely used in commercial biofertilizers and biocontrol agents for sustainable agriculture. Generally, functional *Bacillus* strains are applied as single strain communities since the principles of synthetic microbial consortia constructed with *Bacillus* strains remain largely unclear. Here, we demonstrated that the kin discrimination system directly affects the survival and function of two-member consortia composed of *B. velezensis* SQR9 and FZB42 in the rhizosphere. A mutation in the global regulator *Spo0A* of SQR9 markedly reduced the boundary phenotype with wild-type FZB42, and the combined use of the *spo0A* mutant and FZB42 improved biofilm formation, root colonization and the production of secondary metabolites that are beneficial to plants. We further confirmed the correlation between the swarm discrimination phenotype within community members and effects that are beneficial to plants in greenhouse experiments. Our results provide evidence that social interactions among bacteria could be an influencing factor in achieving a desired community-level function.
