

Figure.1 PCoA plot of fungal (A), bacterial (B) and archaeal (C) community composition among biotopes. Ternary plot depicting compartment relative abundance of fungal (D), bacterial (E) and archaeal (F) OTUs among biotopes of soil, phyllosphere and faeces. Each point corresponds to a class. Its position represents its relative abundance with respect to each biotope, and its size represents average relative abundance across biotopes. All the classes in the same phylum are exhibited in the same colour. GS, GP and GF represent the soil, phyllosphere and faeces samples in grazed grassland soil respectively.

Figure. 2 (A) Network like Venn plot of microbial communities across biotopes of soil, phyllosphere and faeces. OTUs in soil, phyllosphere and faeces and their mutual overlaps are presented with network topography. Venn plot of fungal (B), bacterial (C) and archaeal (D) OTUs among biotopes of soil, phyllosphere and faeces.

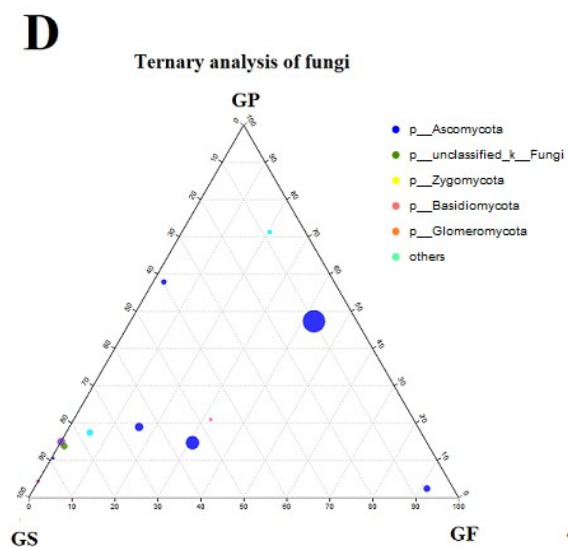

Figure. 3 Relative abundance analysis of fungal (A), bacterial (B) and archaeal (C) communities in biotopes of soil, phyllosphere and faeces on phylum level visualized by barplot; Relative abundance analysis of fungal (D) and bacterial (E) communities in biotopes of soil, phyllosphere and faeces on phylum level visualized by coxcomb analysis; The fungal genera with top 15 relative abundance by random forest classification (F).

Figure. 4 Fungal (A), bacterial (B) and archaeal (C) co-occurrence networks of soil and phyllosphere biotopes in grazed and ungrazed grassland. Nodes represent individual species; edges represent significant spearman correlations ($|\rho| > 0.9$, $P < 0.001$). All the species classified in the same phylum are visualized in the same colour.

Figure. 5 Canonical correspondence analysis (CCA) of the environmental factor impacts on fungal, bacterial and archaeal community composition. GS, GP and GF

represent the soil, phyllosphere and faeces samples in grazed grassland soil respectively.

Figure. 6 Structural equation model (SEM) of relationship between physical factors, nutrient properties and microbiota. For each significant relationship, standardised coefficient and $p =$ values are given alongside arrow, and arrow weights are proportional to standardised coefficients.
