Keywords: *Wolbachia*, *Lycaeides*, *infection acquisition*, *geography of infection*, *Genotyping-By-Sequencing*

Running title: *Wolbachia* in *Lycaeides*

1 **Results from analyses using a concatenated genome as** 2 **reference**

3 Mapping *Lycaeides* GBS reads to the concatenated reference genome of su-
4 pergroups A, B and F resulted in assembly of approximately 7.5 million
5 reads. Variant calling (using the same criteria as listed in the main text)
6 from this concatenated reference produced 116 variable sites. The functional
7 annotation, obtained from the NCBI data base, for these can be found in
8 Supplementary Table 4.

9 **Results from analyses using Scaffold 1260 as reference**

10 Mapping *Lycaeides* GBS reads to Scaffold 1260 from the *L. melissa* reference
11 genome resulted in assembly of approximately 10 million reads. While this is
12 considerably more reads assembled compared to using the concatenation of
13 three *Wolbachia* genome sequences, variant calling from the reads assembled
14 to Scaffold 1260 produced fewer variable sites (fewer SNPs). Variant calling
15 from Scaffold 1260 produced 96 variable sites while variant calling from the
16 concatenated *Wolbachia* genome sequences produced 116 variable sites. This
17 disparity could arise because the assembly to Scaffold 1260 results in more
18 rare sequences mapping to the reference, and thus more mapped reads overall,
19 but few of the variable sites associated with these rare sequences pass the
20 variant filtering criteria. Conversely, it is possible that the concatenated
21 reference spans more of the strain variation across *Lycaeides* (i.e. beyond *L.*

22 *melissa*) resulting in more variable sites meeting filtering criteria.

23 **Comparisons across assemblies**

24 The distribution of read lengths were almost identical across the three assem-
25 blies with more than 80% of reads with lengths $> 80\text{bp}$ for all three reference
26 genomes. Correspondingly, we found that the number of infected individuals
27 detected changed by $< 0.07\%$ across assemblies (16 individuals out of 2,377,
28 see details below), when using the $5\times$ threshold.

Supplementary Figure 1: Histogram of reads mapping to Scaffold 1260 reference of *Lycaeides melissa* for a total of 10 million reads. The histogram for the concatenated reference and for the pan-genome were very similar with peaks in the same locations.

Supplementary Figure 2: Plots indicating infection percentage in a population as a function of the length (color) and number of reads (X-axis)

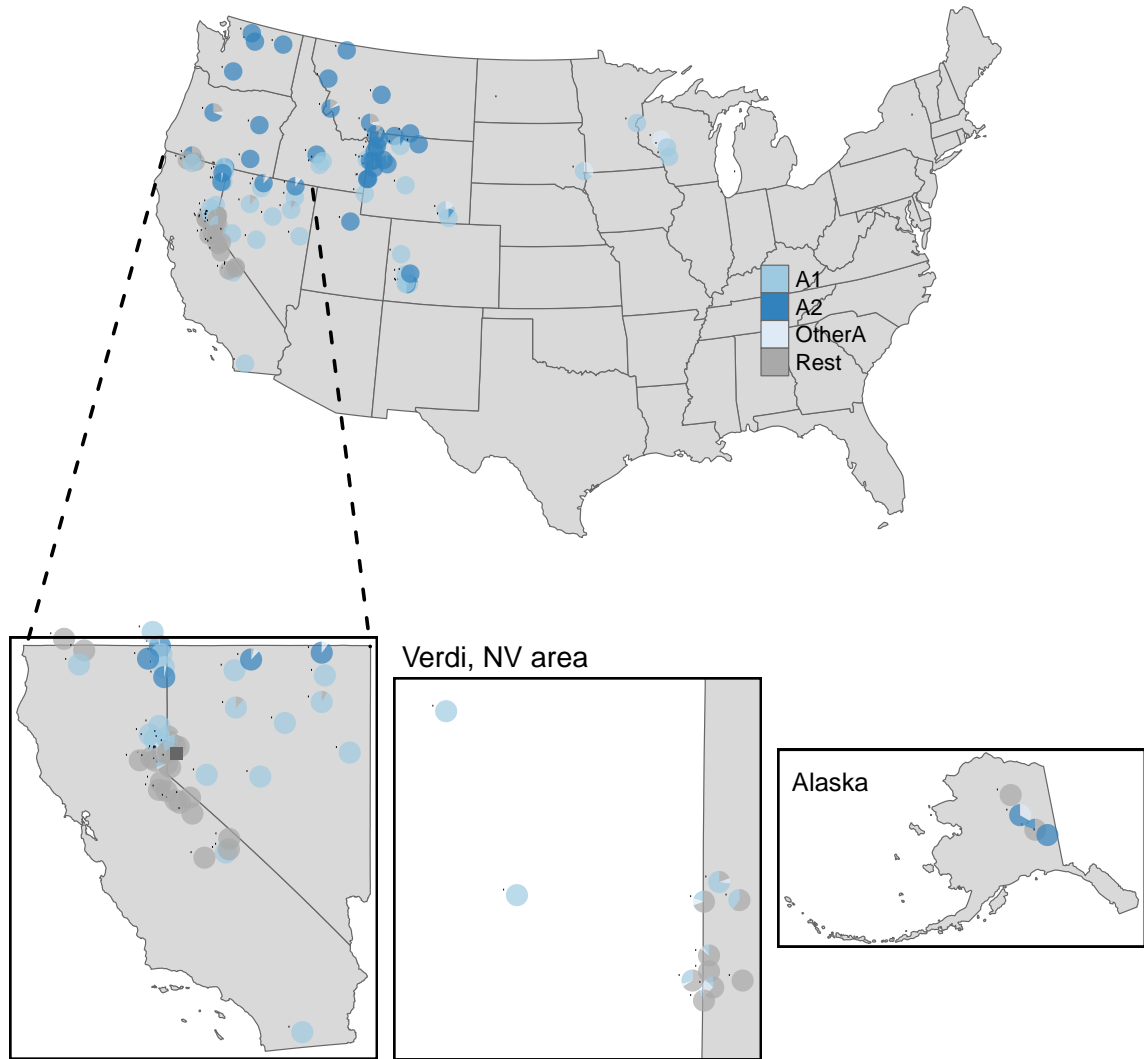

Complete network

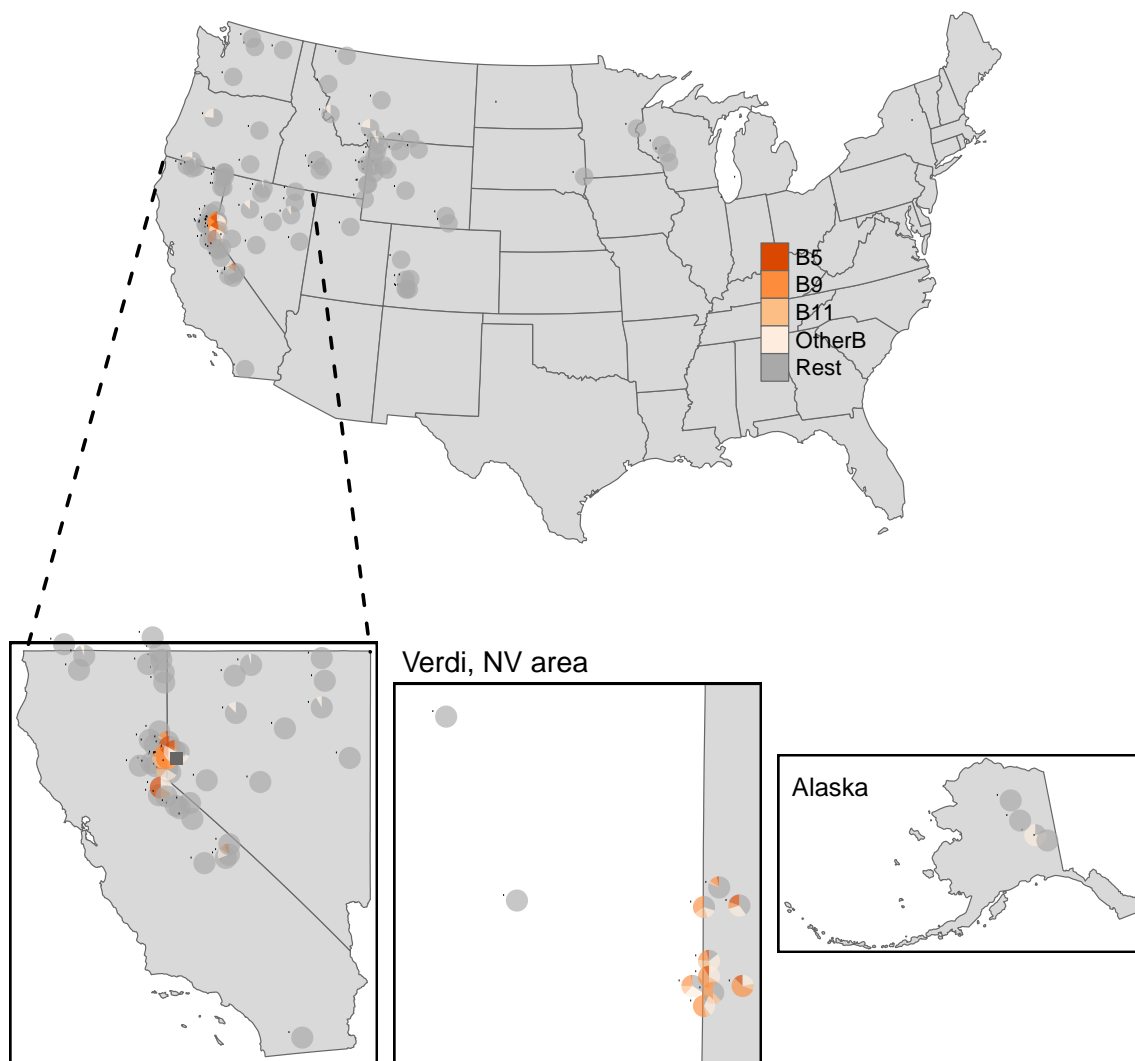

Supplementary Figure 3: All haplotypes shown in one parsimony network with number of individuals in parenthesis (statistical parsimony limit of 55%).

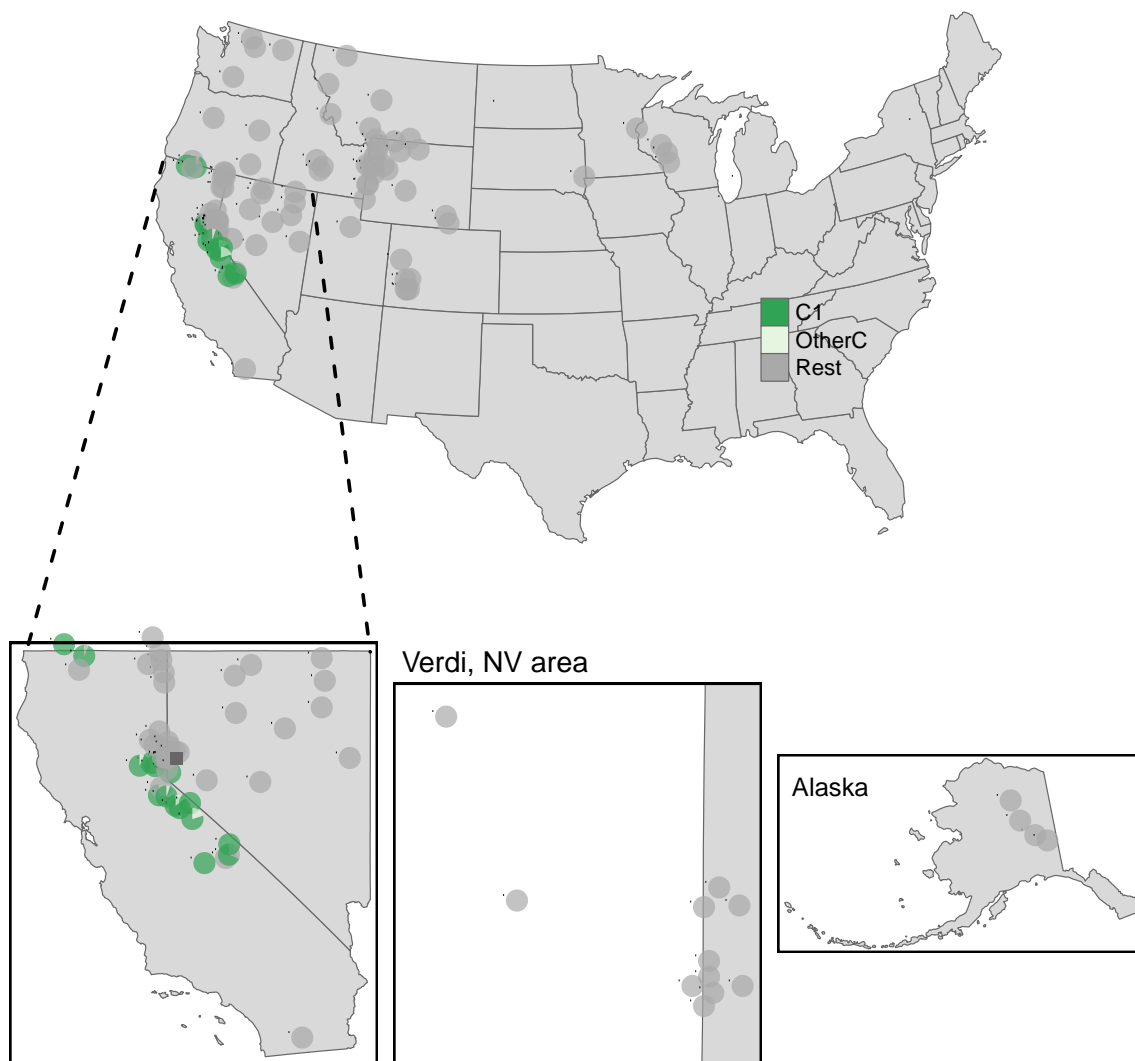

Supplementary Figure 4: Bubble plots showing the *Wolbachia* strain diversity (i.e., expected population heterozygosity or Gini-Simpson index) for each population, with warmer colors representing higher diversity and bubbles scaled by sample size.

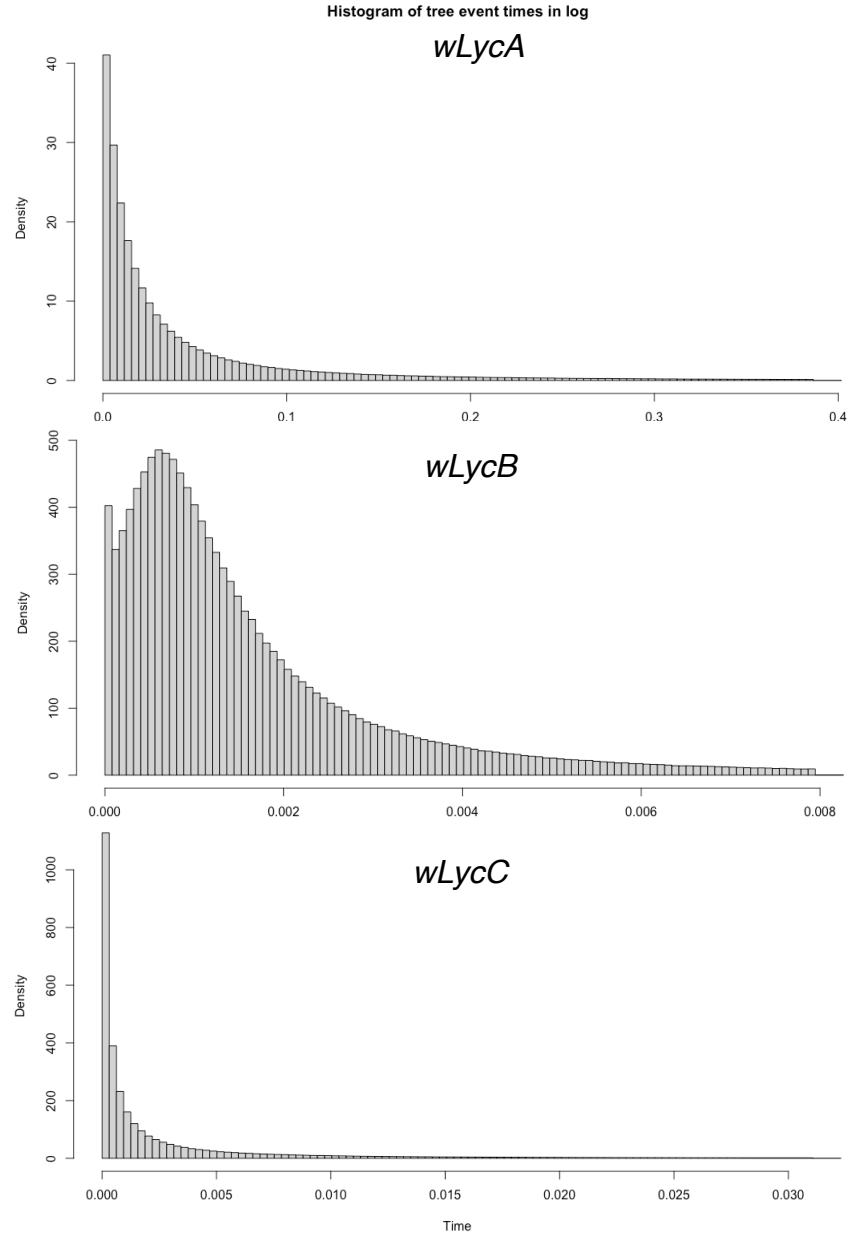

Supplementary Figure 5: Pie charts showing the distribution of haplotypes from strain *wLycA* across the 107 sampled locations for the concatenated reference genome. Haplotypes A1 and A2 are present in 97.2% of individuals infected with strain *wLycA*. The label ‘OtherA’ corresponds to rare haplotypes in *wLycA* (A3-A9), and the label ‘Rest’ corresponds to individuals not infected by strain *wLycA* (i.e., individuals infected with strains *wLycB* and *wLycC*, but not uninfected individuals). Pie charts for each locality are scaled by sample size. Inset plots zoomed in to regions of interest for visibility.

Supplementary Figure 6: Pie charts showing the distribution of haplotypes from strain *wLycB*, scaled by sample size across the 107 sampled locations when the concatenated reference genome is used. Haplotypes B5, B9 and B11 make up 53% of all infections in the B strain. Inset plots zoomed in to regions of interest for visibility.

Supplementary Figure 7: Pie charts showing the distribution of haplotypes from strain *wLycC*, scaled by sample size across the 107 sampled locations for the concatenated reference genome. Haplotype C1 makes up for 97% of all infections in the C strain, and all other C haplotypes are found in localities that also include haplotype C1.

Supplementary Figure 8: Histogram of 95% of tree event times as recorded in the log during the **BEAST** run. There are barely any events beyond the right limit on the X-axis to indicate population size changes for each network. For example, most population size changes in *wLycC* happen between 0 and 0.0025 time units as evidenced by the right skew. We also see that only *wLycB* shows a population size change at an appreciable time in the past (non-zero) as compared to the other two networks.

Supplementary Table 1: Supplemental sample information for 107 *Lycaeides* collection localities. Table includes information on: locality number (corresponding to Fig . 1), locality names, nominal species designations (see text for details), year of collection, locality coordinates, number of individuals sampled, nucleotide diversity (as π), and *Wolbachia* strain diversity. The nominal species column includes some geographic divisions (e.g. “L. melissa - East”) that represent substantial subdivisions within nominal taxa (see Gompert *et al.* (2014), Chaturvedi *et al.* (2018)). “NA” for some localities indicates that no genotype information was available for these localities. Diversity measures the variation in strain types within localities (see main text for details).

Supplementary Table 2: Barcoded adaptors used during GBS library construction. Oligonucleotides are organized in pairs that are annealed to create the double stranded adaptors. For example, oligonucleotides 8bp-2 and 8bp-2B are annealed to make one adaptor. Each contains an 8-10bp unique identifier sequence and the EcoR1 restriction site. These are ligated onto genomic fragments along with an adaptor that corresponds to the MseI restriction site (that does not include unique identifier sequences): MseI1 5' GCA-GAAGACGGCATACGAGCTCTTCCGATCTG 3' and MseI2: 5' TACA-GATCGGAAGAGCTCGTATGCCGTCTTCTGCTTG 3'. Fragments with these adaptors can be amplified with Illumina primers: Illpcr1 (Forward): 5' AATGATACGGCGACCACCGAGATCTACACTCTTTCCCTA-CACGACGCTCTTCCGATCT 3', Illpcr2 (Reverse): 5' CAAGCAGAA-GACGGCATACGAGCTCTTCCGATCTGTAA 3'.

Supplementary Table 3: Mapping summary metrics across reference genomes. We found close correspondence amongst bioinformatic analyses when using any one of the three reference genomes listed above. As a result, our final conclusions in the main text focuses on reads mapped to the pan-genome reference as we believe this captures the range in genetic variation in our system.

	Scaffold 1260	Concatenated	Pan-genome
# of reads (total)	12.32 mil	7.62 mil	11.03 mil
# of reads (>80 bp)	10.01 mil (82.15%)	6.32 mil (82.92%)	8.75 mil (79.27%)
avg. # of reads mapped to Wolbachia	19.50%	21.35%	19.37%
# of infected individuals	2,101 (88.38%)	2,114 (88.94%)	2,117 (89.06%)
length of pseudo-haplotype	97 bp	116 bp	115 bp

Supplementary Table 4: Gene annotations for regions in the pseudo-haplotype obtained across different references in the NCBI data base. Melan is short for reference genome of *Wolbachia* in *Drosophila melanogaster*, similarly Aalbo for *Aedes albopictus* and Lectu for *Cimex lectularius* (see main text for details).

start	end	ref	gene	product	protein id

				glycine-tRNA ligase subunit beta	

Supplementary Table 5: Numbers of infected host individuals detected for 107 *Lycaeides* butterfly collection localities using different thresholds: the column labeled “# Infected 1x” indicates the number of infected individuals detected using a threshold of a minimum of one sequence read, the column labeled “# Infected 5x” indicates the number of infected individuals detected using a threshold of a minimum of five sequence reads, and the column labeled “# Infected 20x” indicates the number of infected individuals detected using a threshold of a minimum of 20 sequence reads. All sequence reads were at least 80bp in length.
