Table S2. Daily GPP and ecosystem respiration (R_{eco}) model-data fit when assimilating NEE observations with all parameters (P1) in terms of prior and posterior root mean square error (RMSE) for all twelve sites. The reduction in daily GPP RMSE varies between 0.03 to $0.7 \text{ gCm}^{-2}\text{d}^{-1}$, and the reduction in daily R_{eco} RMSE varies between 0 to $0.7 \text{ gCm}^{-2}\text{d}^{-1}$. The sites are listed in order from largest mean annual C sink (US-Vcm) to mean annual C source (US-Aud).

Figure S1. Comparison of NEE observations (grey) with corresponding ORCHIDEE model simulations before (green line) and after assimilation (red line) for assimilating NEE observations with all parameters (P1). The vegetation types are listed within brackets for each site. The RMSE measures the fit of the model prior and posterior simulations with the corresponding observations. Across all sites, the prior and posterior NEE RMSEs vary between 0.291-1.377 and 0.196-0.788, respectively. The sites are listed in order from largest mean annual C sink (US-Vcm) to mean annual C source (US-Aud).

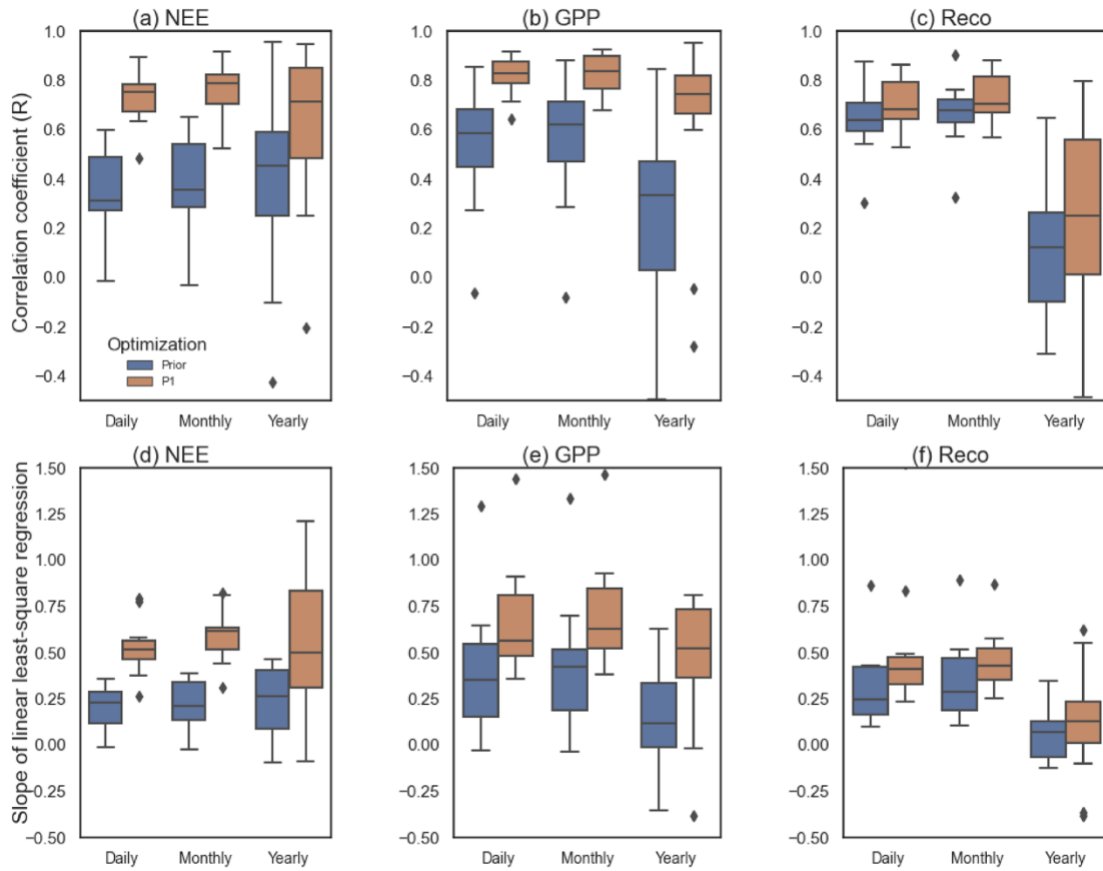

Figure S2. Daily, monthly and annual NEE (a, d), GPP (b, e) and R_{eco} (c, f) prior and posterior Pearson correlation coefficients (R) and slope values for the linear regression between model and observed fluxes for assimilating NEE observations and optimizing all phenology, photosynthesis and post C uptake parameters (P1). The R between observed and modeled NEE at daily, monthly and annual timescales for optimizing all parameters (P1) increase by up to 0.50, 0.55, 0.65 respectively. Note that the y axis limits for both R and slope are the same and therefore 3 sites fall outside the y-axis upper limit for the R_{eco} slope.

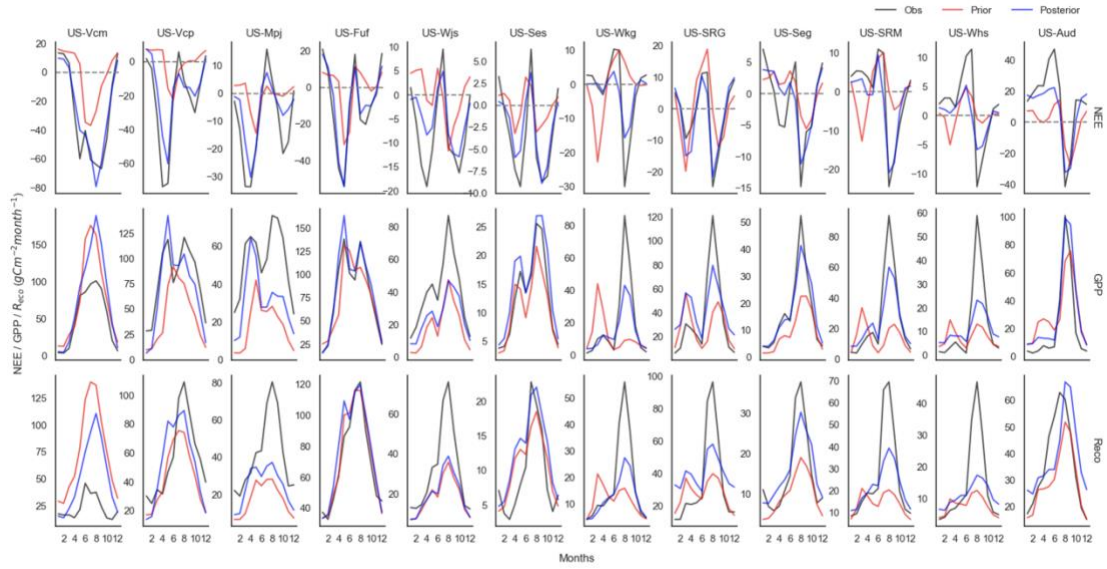

Figure S3. Seasonal cycle with mean monthly total fluxes. Comparison of flux observations with corresponding ORCHIDEE model simulations (prior and posterior) for assimilating NEE observations and optimizing all phenology, photosynthesis and post C uptake parameters (P1). The sites are listed from left to right according to C sink to source.

Figure S4. Annual NEE, GPP and R_{eco} mean square deviation (MSD) decomposition into bias, variance, and phase between simulations and observations for assimilating NEE observations and optimizing all phenology, photosynthesis and post C uptake parameters (P1). Different rows separate the sites as sink (a-c), pivot (d-f) and source (g-i)

based on total annual C flux. The sink sites are: US-Vcm, US-Vcp, US-Mpj, US-Fuf, US-Wjs and US-Ses; the pivot sites are: US-Wkg, US-SRG, US-Seg, US-SRM and US-Whs; and the source site is: US-Aud. The x axes display the optimization scenarios (Prior and P1). The box whiskers show the spread of bias, variance and phase for all 12 sites considered in this study. The bias, variance and phase indicate the mean difference in flux magnitude, the mismatch in terms of flux fluctuation magnitude scales with the mean seasonal amplitude, and the seasonality in flux time series, respectively. Note that the y axis limits are different for all fluxes and site types.

Figure S5. Annual NEE scatter plots for prior and all posterior simulations for assimilating NEE observations with various parameter sets (P1-P7). Different colour legends represent various sites, ordered from the largest mean sink (US-Vcm) to the largest mean source (US-Aud). The middle of the trend line should sit on the 1:1 line if the accurate mean annual source/sink behavior for a site is well captured by the model. A slope value close to or equal to 1 demonstrates the model is better at capturing the IAV. The sink sites are: US-Vcm, US-Vcp, US-Mpj, US-Fuf, US-Wjs and US-Ses; the pivot sites are: US-Wkg, US-SRG, US-Seg, US-SRM and US-Whs; and the source site is: US-Aud.

Figure S6. NEE (a, d), GPP (b, e) and R_{eco} (c, f) annual anomaly prior and posterior Pearson correlation coefficients (R) and slope values for the linear regression between model and observed fluxes across all assimilation scenarios with different parameter combinations (P1-P7). The legend represents various assimilation scenarios (Prior - blue bars, and posterior P1-P7 - orange bars).

Figure S7. Mean monthly seasonal cycles comparing observations (black curve), prior (red curve), and posterior simulations for assimilation scenarios (P1 to P7 - blue to magenta curves) for NEE (left column), GPP (middle column), and R_{eco} (right column) averaged across site C balance types (sink - top row; pivot - middle row; and the source site, US-Aud, on the bottom row).

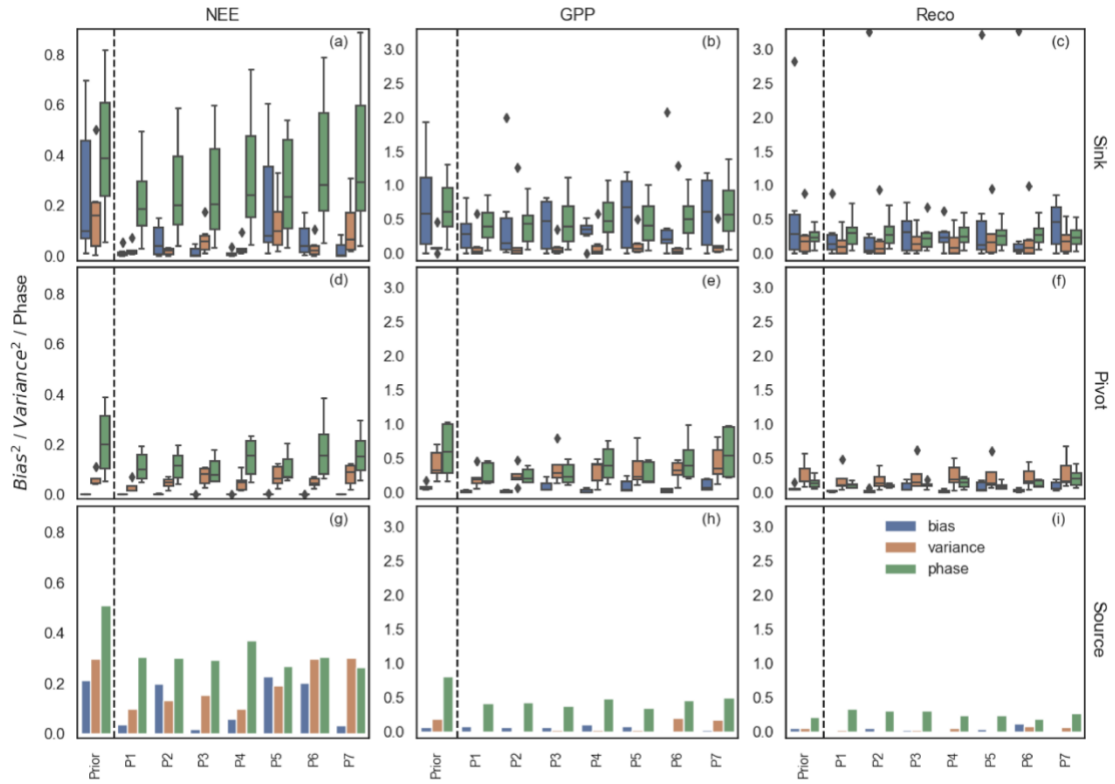

Figure S8. Daily NEE, GPP and R_{eco} mean square deviation (MSD) decomposition into bias, variance, and phase between simulations and observations for assimilating NEE observations with various parameter sets (P1-P7). Different rows separate the sites as sink (a-c), pivot (d-f) and source (g-i) based on total annual C flux. The sink sites are: US-Vcm, US-Vcp, US-Mpj, US-Fuf, US-Wjs and US-Ses; the pivot sites are: US-Wkg, US-SRG, US-Seg, US-SRM and US-Whs; and the only source site is: US-Aud. The x axes display various optimization scenarios (Prior, P1-P7). The parameters included in each optimization are: P1: all parameters; P2: phenology and photosynthesis; P3: phenology and post C uptake; P4: photosynthesis and post C uptake; P5: phenology; P6: photosynthesis and P7: post C uptake. The box whiskers show the spread of bias, variance and phase for all 12 sites considered in this study. The bias, variance and phase indicate the mean difference in flux magnitude, the mismatch in terms of flux fluctuation magnitude scales with the mean seasonal amplitude, and the seasonality in flux time series, respectively. Note that the y axis limits for both gross fluxes are the same.

prior and the posterior values are provided for all sites. For the mixed-PFT sites, only the parameters for the majority PFT fraction are presented, although the other PFT parameters are also optimized. For example, this figure shows the parameters associated with PFT=4 (TeNE) for site US-Mpj, however the optimization is performed with all the parameters of both PFT=4 (TeNE) and 11 (C4G). Note that the soil Q10 parameter is the exponent of the actual Q10 value used to calculate heterotrophic respiration temperature sensitivity (see **Table S1** for more information).
