10 Abstract

11 Crop pollinator dependence (PD) values are key when assessing a pollinator's
12 contribution to agriculture, guiding management plans and policies for sustainable crop
13 production. However, available global compilations of crops PD are outdated and
14 neglect variability between accessions (variety/cultivar) and pollen limitation (PL), i.e.
15 the production lost due to inadequate pollen receipt.

16 Here, we obtained quantitative PD values for animal pollinated crops and their
17 accessions, using data from available pollination experiments worldwide. We also tested
18 pollination methodologies to assess their impact in PD values and to define suitable
19 methodological guidelines for future pollination studies.

20 We provide a list of continuous PD values for 141 crops, including 317 accessions and 37
21 crops not listed in previous assessments. We found that globally, 75% of the animal
22 pollinated crops depend highly on pollinators, with more than 40% of their production
23 being associated with animal pollination. Pollen limitation was detected in 52% of the
24 dataset entries, indicating that estimates calculated with open pollination studies
25 underestimate crop pollinator dependence and so fail to represent the true pollinator
26 contribution to food production.

27 The quantitative data provided here enables a more accurate estimation of pollinator
28 contribution to food production, thus, future studies may use these values for better
29 assessments of the value of pollinators for food security at local, regional and global
30 scales. Additionally, future crop pollination studies should consider crop accessions and
31 include pollen supplementation treatments for a more accurate assessment of the
32 contribution animal pollination makes.

53

54 Introduction

55 Biotic pollination is a crucial biodiversity-dependent ecosystem service that contributes
56 to crop yield, supports food security, and provides other ecosystem services (Dicks et
57 al., 2021; Power, 2010). Together with managed pollinators, diverse and abundant wild
58 pollinator communities ensure the reproduction of pollinator-dependent crops,
59 increasing yields and/or improving the quality of fruit and seeds, even in self-compatible
60 crops (Klatt et al., 2014; Klein et al., 2003). Unfortunately, there is evidence that
61 pollinator numbers are on the declining, driven primarily by human-induced changes,
62 and pollination services may be at risk, with implications to food security and human
63 well-being (Potts, Imperatriz-Fonseca, et al., 2016; Dicks et al., 2021).

64 The ability of a given crop field to achieve its maximum production potential depends
65 on numerous environmental factors, such as nutrient and water availability, biotic
66 interactions, and pest levels (Licker et al., 2010). For pollinator-dependent plant crops
67 that have as their primary product fruits or seeds, pollination is directly linked with crop
68 yield. In these crops, yield is mainly the result of two components (Fig. 1): (1) crop auto-
69 pollination ability (the ability to produce fruits and/or seeds in the absence of
70 pollination vectors, Fig. 1 - AUTO bar) and (2) pollination services available in each place
71 and time (open pollination, Fig. 1 - OPEN bar). Altogether, they result in yields that, in
72 optimal conditions, are theoretically equal to (3) the production under optimal levels of
73 pollination (Fig. 1 - OPT bar).

74 The difference between open and optimal yields is known as pollen limitation (PL; Fig.
75 1), and it is caused by insufficient and/or inefficient pollination services (Bartomeus et
76 al., 2014; Toledo-Hernández et al., 2017). Following Liebig's law (Liebig, 1840), crop

77 yield is determined by the most limiting factor. In pollinator-dependent crops, when no
78 other factors limit yield (as expected in optimized agricultural systems), pollination
79 service may be the limiting factor (Tamburini et al., 2019). PL leads to reduced
80 productivity through a quantitative reduction in the amount of a crop produced and/or
81 a loss in crop quality (Vaissière et al. 2011).

82 The contribution of animal pollinators to crop yields (Fig. 1) can vary significantly due to
83 spatial, temporal, and biotic factors (Bishop & Nakagawa, 2021; Mallinger et al., 2021;
84 Webber et al., 2020). Pollinator communities are largely impacted by factors such as
85 regional biodiversity, landscape structure, environmental conditions during flowering,
86 and local management practices (Holland et al., 2017; Mota et al., 2022; Potts et al.,
87 2010; Senapathi et al., 2017) and, consequently, pollination services provided by
88 pollinator communities are likely to show significant variation.

89 The relative difference in yield resulting from crop auto-pollination ability and optimal
90 pollination corresponds to the potential pollinator's contribution to production, i.e. the
91 true level of PD, a metric highly used to endorse the importance of pollinators to humans
92 (Fig. 1). Estimates of pollinator's contribution to agricultural production can guide both
93 farm management practices and policymaking regarding pollinator conservation (Potts,
94 Ngo, et al., 2016). PD values are tools to guide farmers towards practices that enhance
95 pollinator communities, benefiting crop yield. For crops highly reliant on animal
96 pollinators, implementing management strategies tailored to protect, sustain and, if
97 needed, attract pollinators to the crop field becomes essential. These strategies typically
98 prioritize the reduction of agrochemicals usage and the promotion of floral resources,
99 habitat connectivity and nesting sites (Mota et al. 2022; Bartomeus et al. 2014; Potts et

100 al. 2010). Furthermore, by combining crops' PD with their economic value, we can assess
101 the direct economic impact of pollinators on crop production and crop markets (Gallai
102 et al., 2009; Potts, Imperatriz-Fonseca, et al., 2016; Silva et al., 2021).

103 Studies such as Free (1993) and Klein et al. (2007) widely assessed pollinator's
104 dependence of crops. Klein et al. (2007), the most comprehensive and widely used
105 study, compiled PD values in four categories ("little", "modest", "high", and "essential")
106 for 91 major global crops. This index constitutes the base for current economic
107 assessments of pollination value at regional, national and global scales, facilitating
108 conservation actions and initiatives focussed on pollinators and their importance (e.g.
109 Gallai et al., 2009; Millard et al., 2023; Potts, Ngo, et al., 2016). However, due to the
110 continuous emergence of crops and new studies being available, a revision on PD levels
111 of crops is currently needed. Recent syntheses after the seminal work of Klein et al.
112 (2007) include PD values for emergent crops; nevertheless, they are usually focused on
113 a few economically important crops or specific regions of the globe (see Bishop &
114 Nakagawa, 2021; Giannini et al., 2015; Mallinger et al., 2021). Additionally, within a crop,
115 different accessions (plants that share similar and/or selected traits, including cultivars,
116 varieties and other infraspecific taxonomic levels) may differ greatly in self-compatibility
117 and auto-pollination ability (e.g. Kendall et al., 2020; Klatt et al., 2014) and, hence,
118 different PD levels are expected (e.g. Bishop & Nakagawa, 2021; Carvalheiro et al., 2010;
119 Marini et al., 2015). However, detailed information about PD levels in crop's accessions
120 is scattered in the literature, making it difficult to compile, and to our knowledge, it is
121 seldom accounted for in global studies.

122 Despite the growing availability of studies quantifying PD, there are challenges with the
123 currently used methodologies, which could be underrepresenting the importance of
124 pollinators and their associated economic value. Crops' PD literature usually evaluates
125 crop production after open pollination (i.e. pollination provided by locally available
126 pollinator communities), comparing it with the output after pollinator exclusion (Fig. 1).
127 Consequently, PD values using open pollination will vary according to the local pollinator
128 communities. Hence, we propose that hand pollen supplementation is more suitable to
129 estimate PD since open pollination may lead to underestimations of PD values. For
130 example, for the same plant species, a PD estimation based on an open pollination
131 reference, in an impoverished landscape with unfavourable conditions for pollinators
132 will generate lower PD values than a similar experiment run in a landscape with rich and
133 abundant pollinator communities able to provide suitable pollination services. Because
134 PL is common in wild plants and crops (Bennett et al., 2018; Olhnuud et al., 2022; Potts,
135 Ngo, et al., 2016; Sáez et al., 2022), we expect lower estimates of PD using open
136 pollination than with hand-pollination. Moreover, as flower manipulations may affect
137 flower and fruit development (e.g. Hedhly et al., 2009), we expect different
138 methodologies associated with hand pollen supplementations (e.g. emasculation
139 and/or bagging of flowers) to impact PD estimates negatively. In contrast, experiments
140 conducted on a smaller scale, such as individual flower level, may overestimate PD
141 levels. This can be attributed to resource allocation, where a successfully pollinated
142 flower, such as in hand pollen supplementations, triggers a reallocation of resources,
143 favouring higher-quality pollinations compared to other flowers of the plant
144 (Wesselingh, 2007). Thus, PD values are expected to be higher when pollination

145 treatments are performed at smaller scales (e.g. flower level) than at larger ones (e.g.
146 plant level).

147 We gathered information on pollination experiments for animal pollinated crops to test
148 the aforementioned expectations and propose a methodological framework to estimate
149 the PD of crops. Finally, we provide a list of continuous PD values for animal pollinated
150 crops, including crop accessions whenever available. We believe this list can support
151 more accurate economic assessments of the contribution pollinators make to food
152 production at local, regional and global scales and guide policymaking and farm
153 management practices regarding pollinator conservation.

165 Material and Methods

166 Dataset development

167 To assess animal pollination's contribution to crops production, we used data focused
168 on pollination experiments performed in agricultural contexts and open conditions,
169 from the PolLimCrop database (unpublished data). The search was based on a list of
170 animal pollinated plant crops from which fruit and/or seeds are used as food and goods
171 (FAO's list of crops, available at [<https://www.fao.org/faostat/en/#data/QCL> (2021)]; list
172 of taxa given in Supporting Information, "List of taxa included in the search").

173 To build a dataset of crops' PD, we selected studies with three treatments. First, a hand
174 pollen supplementation treatment, where flowers were pollen supplemented to
175 achieve optimal pollination. Second, an open pollination treatment, where flowers
176 received pollination services naturally, from the environment. Third, a pollinator
177 exclusion treatment, where flowers were excluded from animal pollination through
178 caging or bagging. We retrieved the species and common names of the crop and part of
179 the crop economically used (fruit or seed), with species name standardized using World
180 Flora Online. From the selected studies, the following information was also extracted:
181 1) production results associated with pollination treatments: fruit set, fruit weight, seed
182 set, seed number and/or seed weight; 2) data related to geographical aspects of the
183 study, i.e. continent and country; and 3) records of the additional treatments
184 undertaken that were supplemental to the pollination treatments. These treatments
185 were designated: H – hand pollen supplementation, only; BH – pollinator exclusion and
186 hand pollen supplementation; EH – emasculation and hand pollen supplementation;
187 BEH – pollinator exclusion, emasculation and hand pollen supplementation. The scale of
188 the pollination experiment was also noted in terms of whether the pollination treatment

189 was applied the complete plant, branch, inflorescence (including flower clusters) or
190 individual flower. Additional details on the characteristics of the used dataset can be
191 found in the Supporting Information. Further details on extracted variables are provided
192 in Table S1.

193 Pollinator dependence estimation

194 PD values were calculated using the following equation:

$$195 \quad PD = 1 - [\text{pollinator exclusion production} / \text{pollinator-associated production}]$$

196 where *pollinator exclusion production* refers to the production in the absence of
197 pollinators, and *pollinator-associated production* refers to the production associated
198 with animal pollinator visitation (i.e. hand pollen supplementation or open pollination).

199 Where PD estimates were provided for multiple production variables, the values derived
200 from the commercially used parts were used here (seed and/or fruit). In fruit crops, fruit-
201 related production variables were used for PD calculation, i.e. fruit set and fruit weight.
202 For seed crops, seed set, and seed number and weight were used, in addition to fruit
203 set. In some cases, where both fruit and seed parts are economically used, fruit and
204 seed-related production variables were used to calculate PD values. When several
205 production variables were provided, a mean value of the obtained PD values was
206 calculated and used. Two PD values were calculated for each entry, one using hand
207 pollen supplementation and pollinator exclusion treatments (PD-SUP) and the other
208 using open pollination and pollinator exclusion treatment (PD-OPEN). PD ranged
209 between 0 and 1, with 0 representing a lack of PD and 1 representing the highest level.

210 To identify methodological problems with pollinator exclusion and hand
211 supplementation methodologies, outliers were visually inspected. In four entries (out of

212 564), pollinator exclusion production was 25% higher than pollinator-associated
213 production and were likely related with methodological problems related with the
214 pollinator exclusion methodology. Therefore, PD values were not calculated for those
215 four entries. For the 13 remaining entries where pollinator exclusion production was
216 higher than pollinator-associated production, PD estimates were considered to be zero.
217 Additionally, in 11 entries, pollen supplementation production was 25% lower than open
218 pollination production suggesting methodological problems with the hand
219 supplementation methodology. PD values were not calculated for those entries. To
220 guarantee that the removal of these 15 studies did not affect the main findings of this
221 study, the statistical analyses were performed with the entire dataset (see *Statistical*
222 *analyses* section).

223 A final PD value was obtained for each entry (defined here as PD-final), using either hand
224 pollen supplementation or open pollination treatment, by selecting the maximum value
225 obtained. Variation in production variables is expected, and thus, cases where open
226 pollination overcomes hand pollen supplementation may occur. Cases where
227 production of open pollination are much higher than after hand pollination might reflect
228 methodological issues or lack of efficiency or success in hand pollen supplementation;
229 such cases may affect the data and lead to misleading conclusions. Here, entries in which
230 PD-OPEN was 25% higher than PD-SUP were not used in statistical analyses. These
231 represented only 11 entries (out of 564) and did not significantly affect overall
232 conclusions (see Supporting Information). For every database entry, PD-SUP, PD-OPEN
233 and PD-final was added to the dataset for the subsequent statistical analyses.

234 Statistical analyses

235 A total of 165 records contained hand pollen supplementation, open pollination and
236 pollinator exclusion and were included in statistical analyses. To compare PD levels after
237 open pollination and hand pollen supplementation, General Linear Mixed-Effects
238 Models (GLMMs) were created using PD values from both treatments, with “treatment
239 type” as an explanatory variable. To account for variation associated with crop identity,
240 “crop” was included as a random variable in all models. Similarly, “article code” was also
241 used as a random variable to remove confounding effects of within-study aspects.

242 To evaluate if PD values depended on specific aspects of the methodologies used,
243 analyses were performed using PD-final obtained in our dataset. In particular, GLMMs
244 were performed to analyse the effects of hand pollen supplementation methodology
245 and scale of the pollination experiment on PD values. Hand pollen supplementation
246 methodology included four techniques (see Table S3, ‘supplement type’). Scale included
247 four experimental scales (see Table S3, ‘scale’). Again, “crop” and “article code” were
248 used as random factors. GLMMs were performed using function “lmer” of the R package
249 “lme4” (Bates et al., 2014), with logit transformation of adjusting factor of 0.01 of the R
250 package “car” (Fox & Weisberg, 2019). Wald chi-square analyses were used to calculate
251 the effect of tested variables on PD values. We then ran post hoc pairwise comparisons
252 to test for differences within treatments of supplement type and scale, using R package
253 “emmeans” (Lenth et al., 2018). All analyses were rerun with the complete dataset
254 (including the above mentioned 15 entries) to evaluate if similar trends were observed.

255 The studies on apples constituted 33% of PD values in all performed analyses (see Table
256 S2, Crop “Apple”). To test if such a large set of studies on one crop influenced our results,
257 all analyses without apple’s entries were rerun.

258 To enable comparison with previous global studies, we grouped our continuous PD
259 values into the classes used by Klein et al. (2007; little: 0–0.09 PD, modest: 0.10–0.39,
260 high: 0.40–0.89, essential: 0.90–1.00). All analyses and graphs were obtained in R
261 software (version 4.2.1).

262 Pollinator dependence – Compilation table

263 To provide a comprehensive list of PD values for animal pollinated crops and their
264 accessions, we created a ‘compilation table’ (Table S2) containing the mean PD values
265 calculated for the 165 records used in statistical analyses, and a set of 64 studies
266 reporting only hand-pollen supplementation or open pollination (thus excluded from
267 statistical analyses). A full list of contributing studies is given in the Supporting
268 Information.

269 Mean values were obtained using PD-final from each entry available, plus PD-final of the
270 additional studies (Table S2). Values of PD ranged from 0 to 1, with negative values being
271 considered as 0, indicating no animal pollinator dependence. Treatments that
272 contributed to mean PD values (either hand pollen supplementation treatment, open
273 pollination, or both) are indicated in the dataset. Similarly, mean PD values were
274 obtained and assembled for all the available accessions within crops (Table S3).

275

276

277

278

279

280 Results

281 Open pollination versus hand pollen supplementation

282 A total of 165 records, corresponding to 91 different crops, were used in statistical
283 analyses, including 549 entries with PD values (representing different crops, accessions,
284 years and experimental sites). A map with the geographical distribution of studies and
285 entries included in data analyses is provided (Fig. 2a). A detailed list of record type (e.g.
286 article, thesis or proceeding) are provided in the Supporting Information (Table S4).
287 Crops with most entry values of PD were apple, oilseed rape and almond (representing
288 33.1%, 6.4% and 4.2% of total entries, respectively). Twenty-seven crops were
289 represented by one value of PD only.

290 PD values estimated after hand pollen supplementation-associated production were
291 significantly higher (ca. 5.7% higher on average) than those estimated after open
292 pollination ($\chi^2=38.5260$, $P<0.0001$; Fig. 2b; Table S4). Hand pollen supplementation gave
293 higher PD values than open pollination in 51.5% of cases (Fig. 2c, Fig. S1a). Hand pollen
294 supplementation and open pollination gave similar PD values in 23.9% of cases (Fig. 2c,
295 Fig. S1a). Finally, hand pollen supplementation led to lower PD values than open
296 pollination in 24.6% of cases (Fig. 2c, Fig. S1a).

297 Methodological considerations regarding hand pollen supplementation

298 No significant differences were found in PD values among pollen supplementation
299 techniques ($\chi^2=4.6863$, $P=0.1963$; Fig. S1b; Table S5). However, signs of resource
300 allocation were observed, with significant differences in PD values among experimental
301 scales used in pollination experiments ($\chi^2=8.0840$, $P=0.0443$; Table S5). Despite these
302 signs, no significant differences were observed among scales in post hoc tests (Fig. S1c;

303 Table S6). Similar results were obtained when rerunning analyses without apple studies
304 (Tables S8-S10), and with and without the studies removed (Tables S11-S13).

305 Crop pollinator dependence values

306 Mean PD values are provided for 141 animal pollinated crops. A list of taxa with PD
307 estimated values is given in Supporting Information (Table S2). Information on specific
308 PD values of crop accessions (including cultivars, varieties and other infraspecific
309 taxonomic levels) is provided for 94 crops, comprising 317 individual crop accessions
310 (Table S3).

311 The mean value of PD (PD-final) across all crops of the list was 0.63 ± 0.30 (mean \pm SD).
312 Values varied, as expected, from no PD (value of 0) to complete PD (value of 1); however,
313 a concentration of values around 1 was observed, with 27.0% of the crops having high
314 PD values ($PD \geq 0.90$) (Fig. 3a).

315 When considering the animal pollinator dependent classes defined by Klein et al. (2007),
316 74.5% of the crops were classified as “high” (67 crops, 47.5%) or “essential” (38 crops,
317 27.0%) (Fig. 3b), representing a higher number of crops than in Klein et al. (2007). A
318 similar number of crops were observed in the “modest” class in both studies, here
319 representing 19.9% of the total crops (28 crops). Contrarily, the number of crops
320 classified as “little” was lower than in Klein et al. (2007), comprising only 5.7% of crops
321 in our compilation (8 crops; Fig. 3b).

322

323

324

325 Discussion

326 Crop pollinator dependence values

327 This study provides a new compilation of PD values for animal pollinated crops. For
328 several crop species, PD values given here differ from previous global assessments
329 (Klein et al., 2007), with many crops having higher PD values than listed previously. 75%
330 of the animal pollinated crops were categorized in PD classes “high” or “essential”, an
331 increased ratio compared with compilations such as Klein et al. (2007). Additionally,
332 compared with previous approaches, the list comprises, for the first time, continuous
333 PD values for 141 worldwide crops, including 317 crop accessions, estimates for 37
334 crops (highlighted in bold, Table S2) not listed previously or with no data in former
335 global assessments, and detailed data for several crops that were once merged in large
336 groups (see Fig. 4). By providing PD values discriminated for individual crop species and
337 their accessions, our study contributes with vital and, until now, neglected information.

338 Several PD values of individual crops were higher than in previous compilations (e.g.
339 *Citrus*, durian, strawberry, sunflower). These differences are mainly explained by the
340 fact that PD values were obtained through a different methodology, here using hand
341 pollen supplementation instead of open pollination (primary treatment used in
342 previous estimates) to obtain final PD value. As hand pollen supplementation accounts
343 for effects of PL, it provides more accurate measures of PD. Once PD estimations are
344 usually based on open levels of pollination, previous studies and compilations are
345 substantially underestimating animal pollinator’s importance for crop production.

346 We found wide variation in the PD values reported within crops. This might be expected
347 since the degree of self-compatibility and auto-pollination ability has been shown to
348 vary among crop accessions (e.g. sunflower, Carvalheiro et al., 2011; oilseed rape,

349 Hudewenz et al., 2014). Knowledge of the pollination requirements of crop accessions
350 is crucial for suitable management decisions (Hudewenz et al., 2014), and is becoming
351 a particularly useful in regions where pollinator loss is, or is anticipated to be, more
352 pronounced (Potts, Ngo, et al., 2016). For example, in pollinator-impooverished
353 locations, when pollinator communities are insufficient to provide the needed
354 pollination services to a crop, selecting accessions that are less dependent on animal
355 pollination may be a suitable solution to ameliorate PL. Unfortunately, 29% of the
356 studies analysed here did not provide information about crop accessions (or any other
357 infraspecific taxonomic level, such as cultivar, variety, forma or clone), hindering the
358 compilation of precise data. Considering the importance of this information (Hudewenz
359 et al., 2014), we recommend that future works should always provide information and
360 data for each accession of the crop under study.

361 The optimal pollination level from the plant perspective (i.e. plant fitness) differs from
362 that of farmers perspective (i.e. agronomic and economic yield). To follow farmers'
363 perspective, PD value was calculated using different production variables, depending
364 on the part of the crop economically used (fruit or seed). Quantity (e.g. fruit set) and
365 quality (e.g. fruit weight) production traits were considered, to accurately account for
366 the impact of animal pollination at both levels. Studies on PD often focus on
367 quantitative variables, with mixed responses between these and qualitative variables
368 (e.g. Bartomeus et al. 2014; Stein et al. 2017). Here, however, only 30% of the entries
369 presented quantity and quality variables. Hence, we recommend that future
370 experiments evaluate production variables related to both levels.

371 Open pollination vs. hand pollen supplementation to calculate PD values

372 Hand pollen supplementation led to higher PD values than open pollination in 51.5% of
373 datapoints that had information in both treatments. These results are consistent with
374 our predictions and indicate that PL is common, reducing yield level and, consequently,
375 underestimating potential pollinator's contribution. Therefore, in locations where
376 pollination services are inadequate and/or impoverished, such as landscapes of poor
377 quality due to high levels of fragmentation and/or simplification (Aizen & Feinsinger,
378 2003, Nicholson et al., 2017), hand pollen supplementation is a more suitable treatment
379 to achieve optimal crop yield and obtain an accurate estimate of PD value. However,
380 despite the importance of accurate PD estimates to value pollinator's contribution to
381 production systems, and even though hand pollen supplementation is widely used to
382 study PL in wild plants (e.g. Bennett et al., 2018; Knight et al., 2005), in crops, its use for
383 the calculation of PD has been rare (but see Bishop & Nakagawa, 2021; Garibaldi et al.,
384 2011; Garratt et al., 2021). Based on these results, we recommend that hand pollen
385 supplementation is included in pollination experiments that aim to assess the
386 contribution of animal pollination to crops. A complete experimental design for such
387 purposes is provided below and in Box 1.

388 Methodological guidelines for hand pollen supplementations

389 When performing hand pollen supplementations, assuring efficiency is critical (see Box
390 1). However, in plant families with complex flower structures or with flowers sensitive
391 to manipulation, this can be challenging to achieve. In such cases, animal pollinators may
392 perform better at pollinating than hand pollen supplementation by humans since
393 animals are adapted to exploit floral resources. Thus, the fact that hand pollen
394 supplementation produced lower production values in 24.6% of the data points
395 compared with open pollination is not entirely unexpected. It is possible that in these

396 studies, the supplementation of pollen was not ideal, or that over-pollination led to
397 reduced yield (Bishop et al. 2020). This may represent a limitation of the dataset used in
398 our study, which can lead to the undervaluation of PD levels. Indeed, technical
399 approaches used in hand pollen supplementation, such as type of supplementation,
400 scale at which pollination experiments are done and pollen source, are known to affect
401 yield in certain crops (e.g. Webber et al., 2020).

402 Emasculation of flowers prior to hand pollen supplementation and bagging plants after
403 hand pollination are practices often performed on pollination experiments to exclude
404 production associated with auto-pollination and/or avoid undesirable external pollen,
405 respectively (e.g. Chacoff & Aizen, 2007; Kendall et al., 2020). Here, no significant
406 differences were obtained between standard hand pollen supplementation and
407 supplementation with some of the techniques detailed above, indicating that
408 supplementation using these methods provide reliable estimates of PD or, at least,
409 estimates comparable to hand pollinations.

410 PD values are expected to be higher in pollination treatments conducted at smaller
411 scales (e.g. flower level) than at higher ones (e.g. plant level), as resources for fruit/seed
412 development are usually limited and will be preferentially (re)allocated to flowers with
413 higher pollination quality (Webber et al., 2020). Although no significant differences were
414 observed among different scales, higher PD values were obtained in experiments that
415 used flower as a scale, with marginal p -values obtained when comparing flower vs.
416 inflorescence scales ($P=0.0762$). Therefore, more research focused on resource
417 allocation occurrence is needed to fully disentangle the impact of lower scales on

418 associated production levels. In the meantime, studies should indicate the treatment
419 scale and increase the scale whenever possible to avoid resource allocation problems.
420 Hand pollen supplementation should be included in crop pollination experiments to
421 account for PL, providing a more accurate method to calculate PD values and assess total
422 pollinator's contribution to crop production. Yet, it should be bear in mind that the
423 inclusion of hand pollen supplementation increases the time and complexity of such
424 experiments, particularly in mass flowering or self-pruning crops (where sample size
425 needs to be significantly increased to compensate for self-pruning losses) or in plants
426 with complex, fragile flower structures (demanding more time for hand pollen
427 supplementations). Therefore, when designing a pollination experiment, all factors
428 linked with crop reproductive traits should be considered (Young & Young, 1992),
429 acknowledging the limitations and advantages of selected treatments (see Box 1).

430

431 Conclusions

432 This compilation offers valuable PD values at both crop and accession levels, enabling
433 precise economic assessments for individual crops and subsequently supporting
434 informed decisions in the management of animal pollinated crops. Our results highlight
435 the importance of recognizing that the commonly applied method of assessing PD
436 (comparing fruit set in plants exposed vs isolated from pollinators) can lead to
437 underestimations of PD values. Due to this, the value of animal pollination to
438 production of crops may be higher than previous studies established. Given that most
439 published studies on pollinator's contribution to crops use PD values obtained through
440 methodologies that did not account for pollen limitation, it is probable that pollinator's

441 contribution to crops' local and global production, international trade markets, and
442 economic value of pollinators are substantially undervalued.

443 **Authors' contributions**

444 CS, LGC and SC developed hypothesis and statistical methods, which were discussed
445 with HC and JL. CS and HC led literature search and data extraction. CS, HC and SC
446 performed data validation. CS wrote the first draft, and all remaining authors edited and
447 commented on earlier versions of the manuscript.

448 **Acknowledgements**

449 The authors thank the anonymous reviewers and Robin Payne for their manuscript
450 suggestions. This work was funded by the Integrated Programme of Scientific Research
451 and Technological Development CULTIVAR (CENTRO-01-0145-FEDER-000020), co-
452 financed by the Regional Operational Programme Centro-2020, Portugal-2020 and
453 European Union, through ERDF. Portuguese Foundation for Science and Technology
454 (FCT) financed CS through the fellowship SFRH/BD/145962/2019, HC through national
455 funds by the framework contract foreseen in numbers 4-6 of article 23, Decree-Law
456 57/2016, and SC through the Scientific Employment Stimulus 2021.02697.CEECIND. LGC
457 was funded by the Brazilian Conselho Nacional de Desenvolvimento Científico e
458 Tecnológico CNPq (307625/2021-4).

459 **Conflict of Interest**

460 None declared.

461 **Data accessibility statement**

462 Additional supporting information can be found online in Supporting Information. Upon
463 acceptance of the manuscript, data will be available via figshare, with a provided link.

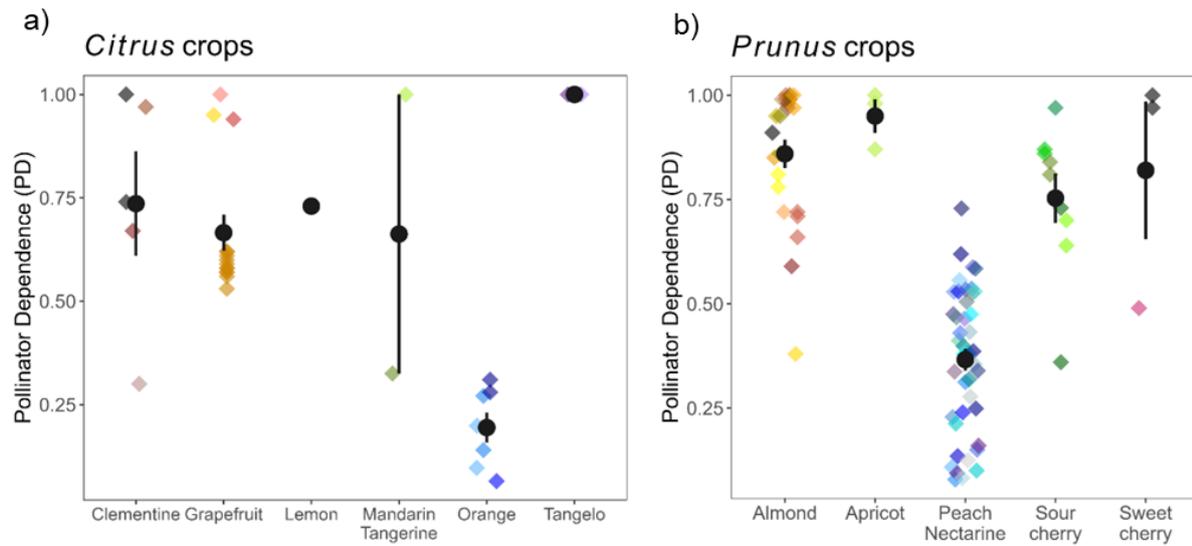

Figure 1. Theoretical representation of pollination components associated with yield in pollinator-dependent crops: autonomous self-pollination levels (AUTO), open levels of pollination (OPEN), and optimal pollination levels for local study conditions (OPT). Associated indexes are also presented: (1) **pollinator's contribution**, yield associated with existing pollination services; (2) **pollinator dependence**, yield directly dependent on pollinators (for simplification, here we considered a crop with negligible wind contribution for pollination) and (3) **pollen limitation**, yield loss associated with limited pollen deposition levels. See Box 1 for methodologies associated with estimations of each component and index.

657 Figure 2. a) Global distribution of data entries and studies of the analysed dataset. The
 658 colour gradient in the map area represents the total number of entries for the different
 659 regions, by ranges. Orange circles represent the total number of studies for the different
 660 regions. b) Estimated means and 95% confidence interval values for PD estimates
 661 obtained with open pollination (OPEN) and hand pollen supplementation (SUP)
 662 treatments ($\chi^2=38.5260$, $P<0.0001$). Different letters indicate significant differences at
 663 $P<0.05$. c) Scatterplot of PD values obtained through SUP treatment (y-axis) in relation
 664 to that obtained through NAT (x-axis); PD values in which PD-SUP>PD-OPEN are
 665 represented as green dots, PD-SUP<PD-OPEN are represented as yellow dots and PD-
 666 SUP=PD-OPEN are represented as black dots.

667 Figure 3.a) Percentage of crops along PD values (0.10 interval range). Final PD was used
 668 for each crop (values given in Table S2). Overall mean PD is indicated through a dashed
 669 line. Different colour bars represent classes as defined by Klein et al. (2007); b) Number
 670 of crops on each PD class: "little" (PD between 0-0.09), "modest" (0.10-0.39), "high"
 671 (0.40-0.89) and "essential" (0.90-1.00). Beige bars represent the crop's distribution
 672 among classes as defined by Klein et al. (2007), and different blue bars represent crops'
 673 distribution in this study. Classes classified as "no increase" and "unknown" in Klein et
 674 al. (2007) were excluded from our study.

675 Figure 4.a) Mean \pm SE values of PD for each crop within the Citrus group; b) Mean \pm SE
 676 values of PD for each crop within the Prunus group. Coloured points represent individual
 677 PD values, with included accessions represented by different colours. See Tables S2 and
 678 S3 for specific data regarding PD values.

687

688 Box 1: Guidelines for pollination experiments when studying animal
689 pollination contribution.

690

An experimental design should include the following treatments:

691

692

693

694

Illustration by Catarina Siopa

695

a) **pollinator exclusion**: a bagged treatment, without biotic visits. In crops also pollinated by wind, the experimental design should also evaluate its contribution using two bagging treatments, one using a mesh fabric that allows wind contribution, excluding only biotic interactions, and another using a mesh that restrains pollen movement by both wind and biotic agents. Wind contribution is given by the difference between the two bagged treatments.

696

697

698

b) **open pollination**: a treatment without any manipulation of the reproductive units where flowers are naturally pollinated.

699

700

c) **optimal pollination** (or pollen supplementation): a treatment where flowers are naturally pollinated and to which a hand pollen supplementation is provided. Pollen applications should be performed once or multiple times, depending on the crop's requirements. The use of compatible pollen is crucial, and several sources of compatible pollen should be applied.

701

702

Additional notes:

703

- Bigger scales are preferred (i.e. branch or plant scales).
- Hand pollen supplementations without additional treatments, as bagging or emasculation, are advised but, if additional treatments are essential for the experiment, they can be considered.
- All relevant details should be provided (e.g., accession, **cultivar**), additionally to details surrounding agricultural management (e.g. application of reproductive hormones, presence of managed pollinators).

Supporting Figures

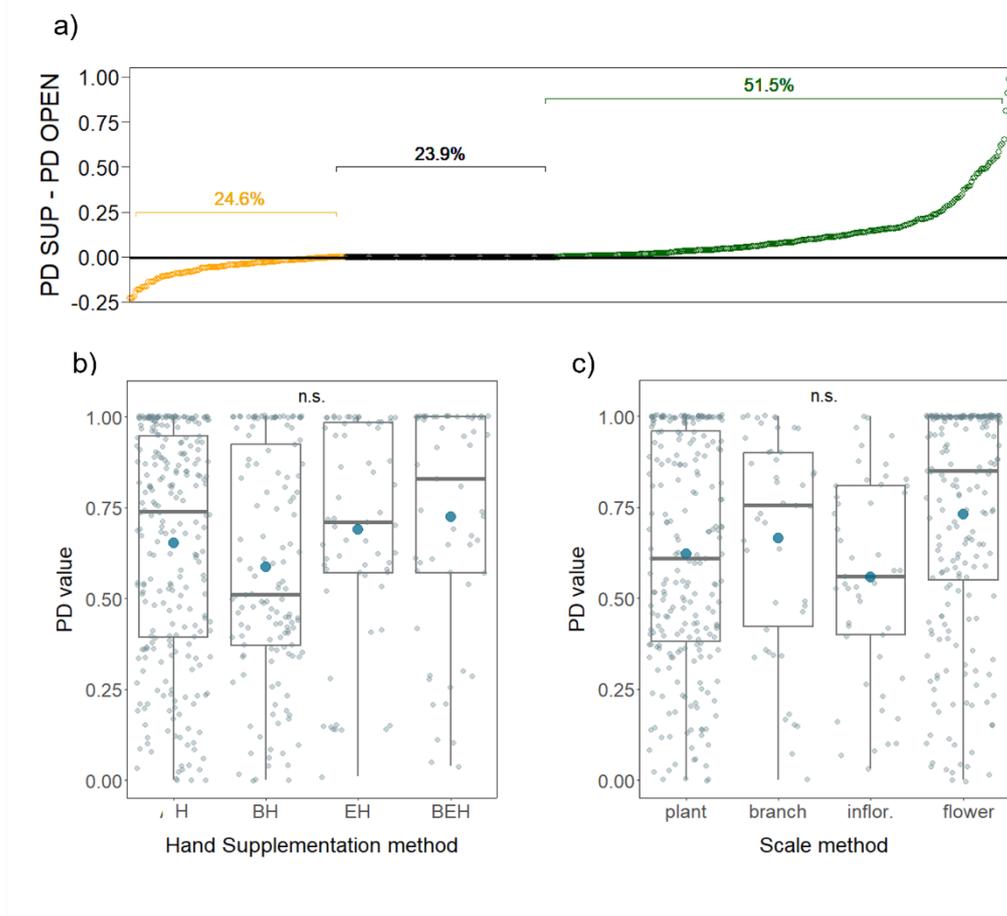

Figure S1 a) Difference between PD values from SUP and OPEN treatments (PD-SUP – PD-OPEN) for each dataset entry; values range from -0.25 to 1.00 (differences lower than -0.25 were considered to result from methodological errors); negative differences, where PD-OPEN was the highest value, represented as yellow dots; values where PD-SUP = PD-OPEN represented by black dots; positive values, where PD-SUP was the highest value, represented as green dot. **b)** Median (solid line) and mean (blue dot) PD values for each hand pollen supplementation technique used in pollination experiments (i.e. H, Hand pollen supplementation with no additional treatments; BH, Bagging treatment + Hand pollen supplementation; EH, Emasculation treatment + Hand pollen supplementation; BEH, Bagging + Emasculation + Hand pollen supplementation). The light grey box represents 25% upper and lower quartiles. Open grey dots represent PD values of the dataset. **c)** Median (solid line) and mean (blue dot) PD values for each scale used in pollination experiments (i.e. plant, whole plant level; branch, branch level; inflor., inflorescence or cluster of flowers level; flower, individual flower level). Light grey box represents 25% upper and lower quartiles. Open grey dots represent PD values of the dataset. No significant differences (n.s.) were observed among different supplementation techniques and scales ($P > 0.05$).

Supporting Tables

Table S1 Information given in the dataset per entry, with description and levels, and response variables used in analyses.

Variable type/name	Description
species	Crop species
crop	Common name of the crop
family	Plant family of the crop
plant accession	Cultivar, variety, forma, clone or any other infraspecific taxonomic level and/or subtype given in the published document
crop part	Economically used part of the crop (i.e. fruit or seed)
country	Country location of the experiment
year of experiment	Year in which the experiment was performed; when a range of years was given, the first indicated year is provided
scale	Scale level of the pollination experiment (plant, branch, inflorescence or cluster, and plant levels)
supplement type	Additional treatments applied to the hand supplement treatment [hand pollen supplementation using bagged and unmanipulated flowers (BH), hand pollen supplementation using open and emasculated flowers (EH), hand pollen supplementation using bagged and emasculated flowers (BEH), hand pollen supplementation using open and unmanipulated flowers (H)]
response variables	- PD SUP (pollinator dependence after hand pollen supplementation) - PD NAT (pollinator dependence from natural pollination) - PD FINAL (maximum value of pollinator dependence for a given entry)

Table S2. Pollinator dependence values of crops. The overall mean, standard error (SE), minimum (min) and maximum (max) values of pollinator dependence are provided, along with the number of accessions with information and the number of entries for each crop. NA denotes no available information. Species highlighted in bold represent species not listed in previous compilations.

Species	Crop common name	Number of accessions with information	Pollinator dependence value				Number of entries

Notes: Our study extends the existing data; however, because we only used studies with pollination experiments, some species previously reported and for which we could not find relevant publications may be missing from our list.

**Annona* spp. includes *Annona* hybrids (e.g. *Annona squamosa* × *Annona cherimola*)

** *Selenicereus* spp. was not always given at the species level by included studies. Difficulties in separating species and accessions are present due to high intra- and/or inter-specific hybridization. Here, we considered two crops: *Hylocereus* spp. (including red-peel pitayas) and *Hylocereus undatus* (white-peel pitaya).

****Macadamia* spp. is adopted for studies in which species level was not given, or hybrids were studied.

†*Vanilla planifolia* was included in this list, although a complete pollination experiment was not found in the literature (due to the lack of a pollinator exclusion treatment). Once vanilla species possess a rostellum membrane that physically divides female and male flower structures, self-pollination is prevented (Rodolphe et al. 2011), and the crop depends entirely on pollinators.

Table S4 Information regarding the number of studies that are articles, reports, conference articles, posters and thesis, from a total of 165 studies included in the statistical analyses. The same information is also provided for 64 additional studies used for PD calculation only.

Studies used in statistical analyses

Study type	Number of studies
Article	136
Report	2
Conference article	5
Poster	1
Thesis	20
Dataset	1

Additional studies for PD calculation

Study type	Number of studies
Article	52
Report	1
Conference article	9
Thesis	2

Table S5 Results of ANOVAs for the effect of treatment (natural pollination, PD NAT, or hand pollen supplementation, PD SUP), supplement type and scale on pollinator dependence values. Model coefficients were obtained through GLMMs using gaussian distribution and logit function transformation with an adjusted factor of 0.01.

Fixed Factor	response variable	Chisq	df	Pr(>Chisq)
Treatment	PD NAT; PD SUP	38.5260	2	4.3080e-09
Supplement type	PD SUP	4.6863	3	0.1963
Scale	PD SUP	8.0840	3	0.0443

Table S6 Post-hoc tests for differences between different methodologies used in hand pollen supplementation on pollination experiments (i.e. H, Hand pollen supplementation with no additional treatments; BH, Bagging treatment + Hand pollen supplementation; EH, Emasculation treatment + Hand pollen supplementation; BEH, Bagging + Emasculation + Hand pollen supplementation), with estimate difference, SE value, df, t ratio and *P*-value for each comparison.

Comparison	estimate	SE	df	t ratio	<i>P</i> -value
H – BEH	-0.373	0.470	153	-0.792	0.8580
H – BH	0.321	0.351	140	0.915	0.7969

Inflorescence – Branch	0.9750	0.759	131	1.285	0.5742
Branch – Plant	0.9571	0.713	110	1.343	0.5380

Analyses with all entries:

To identify methodological problems with pollinator exclusion and hand supplementation methodologies, outliers were visually inspected. Here we present the analyses with all entries of the dataset, including four entries where pollinator exclusion production was 25% higher than pollinator-associated production and 11 entries where pollen supplementation production was 25% lower than open pollination production

Table S11 Results of ANOVAs, *without removing entries*, for the effect of treatment (natural pollination, PD NAT, or hand pollen supplementation, PD SUP), supplement type and scale on pollinator dependence values obtained after hand supplementation. Model coefficients were obtained through GLMMs using gaussian distribution and logit function transformation with an adjusted factor of 0.01.

Fixed Factor	response variable	Chisq	df	Pr(>Chisq)

Supporting Lists

List of taxa included in the search

We based our search on a list of animal-pollinated crops (based on the list of produced crops of FAO 2021 [Food and Agriculture Organization of the United Nations. Crops and livestock products. <https://www.fao.org/faostat/en/#data/QCL> (2021)]). Additionally, we crossed the list with previous compilations to find additional crops not included in the mentioned reference.

Synonyms and common names are indicated in () and [], respectively:

Abelmoschus esculentus [Okra]; *Acca sellowiana* (syn. *Feijoa sellowiana*) [Feijoa]; *Actinidia* (*A. deliciosa*, *A. chinensis*, *A. arguta*) [Kiwifruit, Golden Kiwifruit, Hardy Kiwi]; *Aegle marmelos* [Bael]; *Amomum subulatum* [Black cardamom]; *Anacardium occidentale* [Cashew]; *Annona* (*A. crassiflora*, *A. cherimoya*, *A. squamosa*) [Custard Apple, Araticum, Cherimoya, Sugar Apple]; *Arachis hypogaea* [Peanut]; *Arbutus unedo* [Strawberry tree]; *Artocarpus heterophyllus* [Jackfruit]; *Asimina* (*A. triloba*, *A. parviflora*) [Pawpaw]; *Averrhoa carambola* [Starfruit, Carambola]; *Berberis vulgaris* [Barberry]; *Bertholletia excelsa* [Brazil Nut]; *Bixa orellana* [Annato]; *Brassica* (*B. napus*, *B. nigra*, *B. juncea*, *B. campestris*, *B. rapa*) [Rapeseed, Oilseed Rape, Mustard Seed, Field Mustard, Canola]; *Cajanus cajan* [Pigeon Pea]; *Camellia oleifera* [Camellia]; *Canavalia* (*C. gladiata*, *C. ensiformes*, *C. rosea*) [Sword Bean, Jack Bean]; *Capparis spinosa* [Caper]; *Capsicum* (*C. annuum*, *C. chinense*, *C. frutescens*) [Chilli Pepper, Habanero Pepper, Tabasco Pepper]; *Carica papaya* [Papaya]; *Carthamus tinctorius* [Safflower]; *Carum carvi* [Caraway]; *Castanea* (*C. crenata*, *C. sativa*, *C. dentata*, *C. henryi*, *C. mollissima*, *C. pua*, *C. seguinii*) [Chestnut]; *Ceratonia siliqua* L. [Carob]; *Chaenomeles japonica* [Japanese Quince]; *Chrysophyllum cainito* [Star Apple]; *Cicer arietinum* L. [Chickpea]; *Cichorium* (*C. intybus*, *C. endiva*) [Chicory, Endive]; *Citrullus lanatus* [Watermelon]; *Citrus* (*C. maxima*, *C. reticulata*, *C. medica*, *C. clementine*, *C. limon*, *C. paradisi*, *C. sinensis*) [Pomelo, Mandarin, Citron, Clementine, Lemon, Grapefruit, Orange, Tangelo]; *Cocos nucifera* [Coconut]; *Coffea* (*C. arabica*, *C. canephora*) [Coffee]; *Cola* (*C. acuminata*, *C. nitida*) [Cola Nut]; *Cordeauxia edulis* [Yeheb Nut]; *Coriandrum sativum* [Coriander]; *Crataegus* (*C. azarolus*, *C. monogyna*) [Azarole, Hawthorn]; *Cucumis* (*C. melo*, *C. moschata*, *C. sativus*) [Cantaloupe, Melon, Crookneck Pumpkin, Cucumber]; *Cucurbita* (*C. maxima*, *C. pepo*, *C. moschata*, *C. acutangula*) [Pumpkin, Squash, Gourd, Zucchini]; *Cuminum cyminum* [Cumin]; *Cyamopsis tetragonoloba* [Guar Bean]; *Cydonia oblonga* [Quince]; *Cynara cardunculus* [Cardoon]; *Dimocarpus longan* [Longan]; *Diospyros* (*D. virginiana*, *D. kaki*) [Persimmon]; *Durio zibethinus* [Durian]; *Elaeis* (*E. guineensis*, *E. oleifera*) [Oil Palm]; *Elettaria cardamomum* [Cardamom]; *Eriobotrya japonica* [Loquat]; *Euterpe oleracea* [Açaí]; *Fagopyrum esculentum* [Buckwheat]; *Ficus carica* [Fig]; *Foeniculum vulgare* [Fennel]; *Fragaria × ananassa* [Strawberry]; *Glycine max* [Soybean]; *Gossypium* (*G. hirsutum*, *G. barbadense*) [Cottonseed]; *Guizotia abyssinica* [Niger]; *Helianthus annuus* [Sunflower]; *Inga* (*I. edulis*, *I. stipularis*) [Ice Cream Bean]; *Jatropha curcas* [Jatrofa]; *Juglans regia* [Persian Walnut]; *Lablab purpureus* [Hyacinth Bean]; *Linum usitatissimum* [Linseed]; *Litchi chinensis* [Lychee]; *Lonicera caerulea* [Honeysuckle]; *Luffa* (*L. acutangula*, *L. aegyptica*) [Chinese Okra, Smooth Gourd]; *Macadamia* (*M. integrifolia*, *M. tetraphylla*, *M. ternifolia*) [Macadamia]; *Malpighia* (*M. emarginata*, *M. puniceifolia*) [Indian Cherry, Acerola Cherry]; *Malus domestica* [Apple]; *Mammea americana* [Mammee]; *Mangifera indica* [Mango];

Manilkara zapota [Chicle]; *Medicago sativa* [Lucerne]; *Mespilus germanica* [Medlar]; *Momordica charantia* [Bitter Melon]; *Myrciaria dubia* [Camu Camu]; *Myristica fragrans* [Nutmeg]; *Nephelium lappaceum* [Rambutan]; *Nigella sativa* [Black Cumin]; *Opuntia ficus-indica* [Cactus Pear]; *Paeonia ostii* [Peony]; *Papaver somniferum* L. [Poppy seed]; *Parkia biglobosa* [African Locust Bean]; *Passiflora* (*P. edulis*, *P. ligularis*, *P. setacea*) [Passion Fruit, Granadilla, Passion Flower]; *Pastinaca sativa* [Parsnip]; *Persea americana* [Avocado]; *Petroselinum crispum* [Parsley]; *Phaseolus* (*P. vulgaris*, *P. coccineus*, *P. acutifolius*, *P. lunatus*) [Common Bean, Runner Bean, Tepary Bean, Lima Bean]; *Physalis* (*P. angulata*, *P. peruviana*) [Camapu, Goldenberry]; *Pimenta dioica* [Allspice]; *Pimpinella anisum* [Anise]; *Pistacia vera* [Pistachio]; *Polaskia chichipe* (syn. *Myrtillocactus chichipe*) [Chichituna]; *Poumora cecropiaefolia* [Mapati]; *Prunus* (*P. armeniaca*, *P. avium*, *P. cerasus*, *P. domestica*, *P. dulcis*, *P. salicina*, *P. persica*) [Apricot, Sweet Cherry, Sour Cherry, Plum, Almond, Japanese Plum, Peach, Nectarine]; *Psidium guajava* [Guava]; *Punica granatum* [Pomegranate]; *Pyrus* (*P. communis*, *P. pyrifolia*, *P. bretschneiderie*, *P. ussuriensis*) [Pear]; *Ribes* (*R. nigrum*, *R. rubrum*, *R. uva-crispa*) [Currant, Gooseberry]; *Ricinus communis* [Castor Bean, Ricinus]; *Rosa canina* [Rose Hip]; *Rubus* (*R. chamaemorus*, *R. fruticosus*, *R. idaeus*) [Raspberry, Blackberry, Loganberry]; *Sambucus* (*S. canadensis*, *S. nigra*) [Elderberry]; *Scorzonera hispanica* [Black Salsify]; *Sechium edule* [Chayote]; *Selenicereus* (syn. *Hylocereus*) spp. [Pitaya]; *Selenicereus megalanthus* [Yellow Pitaya]; *Sesamum indicum* [Sesame seed]; *Sinapis alba* [White Mustard]; *Solanum* (*S. betaceum*, *S. lycopersicon* (syn. *Lycopersicon lycopersicum*), *S. melongena*, *S. muricatum*, *S. ovigerum*, *S. quitoense*) [Tamarillo, Tomato, Aubergine, Eggplant, Pepino, Brinjal, Naranjillo, Lulo]; *Sorbus* (*S. aucuparia*, *S. domestica*) [Rowanberry, Service Apple]; *Spondias* (*S. mombin*, *S. tuberosa*) [Hog Plum, Brazil Plum]; *Tamarindus indica* [Tamarind]; *Theobroma* (*T. cacao*, *T. grandiflorum*) [Cocoa, Cupuaçu]; *Trichosanthes* (*T. cucumerina*, *T. dioica*) [Snake Gourd, Pointed Gourd]; *Trifolium alexandrinum* [Berseem]; *Vaccinium* (*V. angustifolium*, *V. corymbosum*, *V. macrocarpon*, *V. meridionale*, *V. myrtilus*, *V. oxycoccus*, *V. virgatum*, *V. vitis-idaea*) [Blueberry, Cranberry, Andean Berry]; *Vanilla* (*V. planifolia*, *V. pompona*) [Vanilla]; *Vernicia fordii* [Tungue]; *Vicia faba* [Fava Bean]; *Vigna* (*V. mungo*, *V. radiata*, *V. subterranea*, *V. unguiculata*) [Mung Bean, Bambara Groundnut, Black Gram, Black-eyed Pea]; *Vitellaria paradoxa* [Karite Nut]; *Ziziphus* (*Z. jujuba*, *Z. mauritiana*) [Jujube].

List of search terms

The literature search was conducted on Scopus, Web of Science and Google Scholar. A general search was performed on the three databases and a literature search for included crop species (using list above) was performed on Web of Science and Google Scholar (see manuscript for strings used). The first 1000 records were considered. Study alerts were checked until March 1st, 2022.

- General search:

Performed on Web of Science, Scopus and Google Scholar
Only the first 1000 results were used.

String 1: Crop AND (hand OR suppl) AND (natural OR open) AND pollination

A total of 1164 results were returned (94, 70 and 1000 for Web of Science, Scopus and Google Scholar, respectively)

String 2: Crop AND hand AND (pollen application OR supplementation) AND (natural OR open) AND (fruit OR seed) AND pollination NOT wild plant communit NOT natural pop

A total of 1017 results were returned (10, 7 and 1000 for Web of Science, Scopus and Google Scholar, respectively).

- Specific search with crop terms:

Performed on Web of Science and Google Scholar
Only the first 1000 results were used.

String 3: [Species / Crop name] AND (hand OR suppl) AND (natural OR open) AND pollination

A total of 28780 results were returned (535 and 28245 for Web of Science and Google Scholar, respectively).

A total of 30961 studies were identified. From the 30961 retrieved records, a total 294 records met the conditions to be included on PolLimCrop (Siopa et al. in revision), where detailed information can be found.

List of taxa with pollinator dependence estimated values

Common names are provided in []; crops in which pollinator dependence mean value includes values obtained from extra studies (see methods section) are indicated with *:

Abelmoschus esculentus Moench [Okra]*; *Acca sellowiana* (O.Berg) Burret [Feijoa]; *Actinidia chinensis* Planch. [Golden Kiwifruit]*; *Actinidia chinensis* var. *deliciosa* (A.Chev.) A.Chev. [Kiwifruit]; *Anacardium occidentale* L. [Cashew]; *Annona cherimola* Mill. [Cherimoya]*; *Annona crassiflora* Mart. [Marolo]; *Annona squamosa* L. [Sugar apple]; *Annona* spp. [Custard apple]; *Arachis hypogaea* L. [Peanut]*; *Artocarpus heterophyllus* Lam. [Jackfruit]; *Asimina parviflora* (Michx.) Dunal [Pawpaw]; *Averrhoa carambola* L. [Carambola]*; *Bertholletia excelsa* Bonpl. [Brazil nut]; *Bixa orellana* L. [Annatto]; *Brassica juncea* (L.) Czern. [Mustard seed]; *Brassica napus* L. [Oilseed rape]; *Brassica rapa* L. [Canola]*; *Cajanus cajan* (L.) Millsp. [Pigeon pea]; *Camellia oleifera* C.Abel [Camellia]; *Capparis spinosa* L. [Caper]; *Capsicum annuum* L. [Chili]; *Capsicum chinense* Jacq. []; *Carica papaya* L. [Papaya]; *Carthamus tinctorius* L. [Safflower]*; *Carum carvi* L. [Caraway seed]*; *Castanea crenata* Siebold & Zucc. [Japanese chestnut]*; *Castanea mollissima* Blume [Chinese chestnut]; *Castanea sativa* Mill. [European chestnut]*; *Castanea sativa* × *C. crenata* [Chestnut]*; *Cicer arietinum* L. [Chickpea]*; *Citrullus lanatus* (Thunb.) Matsum. & Nakai [Watermelon]; *Citrus clementina* hort. [Clementine]; *Citrus limon* (L.) Osbeck [Lemon]; *Citrus paradisi* Macfad. [Grapefruit]; *C. paradisi* × *C. reticulata* [Tangelo]; *Citrus reticulata* Blanco [Mandarin, Tangelo]*; *Citrus sinensis* (L.) Osbeck [Orange]*; *Cocos nucifera* L. [Coconut]*; *Coffea arabica* L. [Arabic coffee]; *Coffea canephora* Pierre ex A.Froehner [Coffee]; *Coriandrum sativum* L. [Coriander]*; *Cucumis melo* L. [Melon]; *Cucumis sativus* L. [Cucumber]*; *Cucurbita maxima* Duchesne [Pumpkin]*; *Cucurbita moschata* Duchesne [Gourd]; *Cucurbita pepo* L. [Squash and Courgette]; *Cuminum cyminum* L. [Cumin]*; *Cydonia oblonga* Mill. [Quince]*; *Dimocarpus longan* Lour. [Longan]*; *Diospyros kaki* L.f. [Persimmon]; *Durio zibethinus* L. [Durian]; *Elaeis guineensis* Jacq. [Oil palm]; *Elettaria cardamomum* (L.) Maton [Cardamom]*; *Eriobotrya japonica* (Thunb.) Lindl. [Loquat]; *Euterpe oleracea* Mart. [Açai]; *Fagopyrum esculentum* Moench [Buckwheat]*; *Ficus carica* L. [Fig]*; *Foeniculum vulgare* Mill. [Fennel]*; *Fragaria* × *ananassa* (Duchesne ex Weston) Duchesne ex Rozier [Strawberry]; *Glycine max* (L.) Merr. [Soybean]*; *Gossypium hirsutum* Cav. [Cottonseed]*; *Helianthus annuus* L. [Sunflower]; *Jatropha curcas* L. [Jatrofa]; *Linum usitatissimum* L. [Linseed]*; *Litchi chinensis* Sonn. [Lytchee]*; *Lonicera caerulea* L. [Honeysuckle]; *Luffa acutangula* Roxb. [Chinese okra]; *Luffa aegyptiaca* Mill. [Smooth gourd]; *Macadamia integrifolia* Maiden & Betche [Macadamia]; *Macadamia* spp. [Macadamia]; *Malpighia emarginata* DC. [Acerola cherry]; *Malus domestica* (Suckow) Borkh. [Apple]; *Mangifera indica* L. [Mango]; *Manilkara zapota* (L.) P.Royen [Sapodilla]*; *Momordica charantia* L. [Bitter melon]; *Myristica fragrans* Houtt. [Nutmeg]*; *Nephelium lappaceum* L. [Rambutan]*; *Nigella sativa* L. [Black cumin]; *Opuntia ficus-indica* (L.) Mill. [Cactus pear]*; *Paeonia ostii* T.Hong & J.X.Zhang [Peony]; *Papaver somniferum* L. [Poppy seed]*; *Passiflora edulis* Sims [Passion fruit]; *Passiflora ligularis* Juss. [Granadilla]; *Persea americana* Mill. [Avocado]; *Phaseolus coccineus* L. [Runner bean]*; *Phaseolus vulgaris* L. [Bean]*; *Physalis angulata* Ruiz & Pav. [Camapu]; *Physalis peruviana* Mill. [Goldenberry]; *Pimpinella anisum* L. [Anise]*; *Polaskia chichipe* (Rol.-Goss.) Backeb. [Chichituna]; *Prunus armeniaca* Thunb. [Apricot]; *Prunus avium* (L.) L. [Sweet cherry]; *Prunus cerasus* Scop. [Sour cherry]; *Prunus domestica* L. [Plum]*; *Prunus dulcis* (Mill.) Rchb. [Almond]; *Prunus persica* (L.) Batsch [Peach, Nectarine]*; *Psidium guajava* L.

[Guava]; *Psopocarpus tetragonolobus* (L.) DC. [Winged bean]*; *Punica granatum* L. [Pomegranate]; *Pyrus communis* Morog. [Pear]; *Ribes rubrum* L. [Currant]; *Ribes uva-crispa* L. [Gooseberry]*; *Ricinus communis* L. [Castor bean]; *Rosa multiflora* [Rose hip]*; *Rubus fruticosus* Marshall [Blackberry]*; *Rubus idaeus* Vell. [Raspberry]*; *Selenicereus* spp. [Red-peel pitahaya]; *Selenicereus undatus* (Haw.) D.R.Hunt [White-fleshed pitahaya]; *Sesamum indicum* L. [Sesame seed]*; *Solanum lycopersicum* L. [Tomato]; *Solanum melongena* L. [Eggplant]; *Solanum quitoense* Lam. [Naranjilla]*; *Spondias mombin* L. [Hog plum]; *Theobroma cacao* L. [Cocoa]; *Trichosanthes cucumerina* L. [Snake gourd]; *Trichosanthes dioica* Roxb. [Pointed gourd]; *Trifolium alexandrinum* L. [Berseem]; *Vaccinium corymbosum* L. [Highbush blueberry]; *Vaccinium macrocarpon* Aiton [Cranberry]; *Vaccinium myrtillus* L. [Bilberry]; *Vaccinium virgatum* Aiton [Rabbit-eye blueberry]; *Vaccinium vitis-idaea* L. [Lingonberry]; *Vanilla planifolia* Andrews [Vanilla]*; *Vicia faba* L. [Broad bean]; *Vigna subterranea* (L.) Verdc. [Bambara bean]*; *Vigna unguiculata* (L.) Walp. [Cowpea]*; *Vitellaria paradoxa* C.F.Gaertn. [Karite nut]; *Ziziphus jujuba* Mill. [Jujube]*.
